# Chapter 14

## Oceans and Coastal Policy

**Coordinating Lead Author:** Diana Mangalagu (University of Oxford and Neoma Business School)

**Lead Authors:** Elaine Baker (GRID-Arendal at the University of Sydney), Pedro Fidelman (Centre for Policy Futures, The University of Queensland), Leandra Regina Gonçalves (University of Campinas), Peter Harris (GRID-Arendal), James Hollway (Graduate Institute of International and Development Studies), Rakhyun E. Kim (Utrecht University), Jake Rice (Department of Fisheries and Oceans – Canada)

**GEO Fellow:** AlAnoud Alkhatlan (Arabian Gulf University)

## Executive summary

**Responding to key drivers and pressures facing the oceans (e.g. climate change, pollution and overfishing; see Chapter 7 of this report) requires diverse policy instruments and governance approaches** (*well established*). These instruments and approaches include command and control, stakeholder partnerships, economic incentives and approaches to enable actors. {14.2}.

**Policy coherence and integration are important in addressing cumulative impacts of local and regional threats to support the resilience of marine ecosystems (e.g. coral reefs) to climate change** (*inconclusive*). However, without international policies to curb carbon emissions, the effectiveness of resilience-based management is likely to be very limited, given the limits to the capacity of marine species to adapt to warmer ocean waters (*well established*). {14.2.1}.

**Problems involving numerous activities, sectors and sources (e.g. marine litter) may require policies involving comprehensive and coordinated measures** (*well established but incomplete*). When such problems involve multiple jurisdictions, governance approaches to engage neighbouring countries (e.g. the Regional Seas Programme) may be appropriate (*well established but incomplete*). {14.2.2}.

**Promoting more sustainable fisheries may require several policy instruments, given the range of contexts in which problems in this sector arise** (*well established*). Territorial use rights for fishing (TURF) programmes are a good fit for fisheries with relatively sedentary stocks, high exclusionary potential, and governments keen to devolve costly management and enforcement functions (*well established*). Individual transferable quotas (ITQs) work best for relatively high-value stocks when supported by strong, independent, scientifically set quotas, strong monitoring, control and surveillance. Regulation of access and resource use rights may be successful when effective enforcement and compliance mechanisms are in place (*well established*). {14.2.3}.

**Some problems may be best addressed by policy instruments that entail community and stakeholder engagement** (*well established*). These include enabling local communities to develop and adopt measures tailored to their context and partnerships with the private sector (*well established*). {14.2.3}.

**Policy-sensitive indicators may be used to track progress in addressing key pressures and drivers** (*well established*). These include area-based indicators, such as the coverage of marine protected areas and of vulnerable marine ecosystems. Protected areas under national jurisdiction or in the high seas have the potential to address several pressures relating to marine biodiversity, including overfishing and habitat destruction (*well established but incomplete*). {14.3.1}.

**Many indicators may not entirely capture the multiple dimensions of different pressures and drivers** (*well established*). Area-based approaches alone do not guarantee effective area management; nor can they guard against the impact of climate change or pollution (*well established*). Efforts to develop methods for evaluating the effectiveness of protected areas are, therefore, critical (*well established*). {14.3.2}.

**A lack of standardization may make it difficult to track progress towards marine conservation** (*well established*). This is the case of beach litter used as an indicator of litter in the marine environment. The lack of standardization and compatibility between methods used and results obtained in various bottom-up projects makes it difficult to reach an overall assessment of the status of marine litter over large geographical areas {14.3.2}.

## 14.1 Introduction

The impacts of human activities on the oceans have serious social and economic implications, which directly and indirectly affect human health and well-being. As noted in chapter 7 of this report, impacts of great concern include those associated with climate change, pollution and overfishing. Coral bleaching is perhaps one of the most dramatic and immediate impacts of climate change on oceans in recent years; marine litter and plastic pollution are rising to the forefront of pollution issues; and the depletion of fish stocks from overfishing remains critical. Drawing on selected policy typologies and related case studies, this chapter examines key approaches and instruments employed in response to these issues

(Table 14.1). In addition, case studies are used to illustrate responses in different governance (subnational, regional and global) and geographical contexts, and highlight challenges and opportunities for policy design and implementation.

This chapter also provides valuable insights into the effectiveness of policies at regional and global levels by drawing on selected policy-sensitive indicators, such as the coverage of marine protected areas, beach litter assessment and representation of vulnerable marine ecosystems in regional fisheries management organizations.

## 14.2 Key policies and governance approaches

### 14.2.1 Resilience-based management (climate change adaptation policy)

Resilience-based management (RBM) of coral reefs is an emerging concept in the context of very limited alternatives (van Oppen *et al.* 2015; van Oppen *et al.* 2017), given that the root cause of coral bleaching is the increasing level of atmospheric carbon dioxide (CO<sub>2</sub>). RBM refers to strategic policy interventions at local and regional levels to support ecological resilience (i.e. the capacity to resist disturbances and recover from these disturbances) (Anthony 2016). It is believed to help offset to some extent the increasing effects of climate change (Anthony *et al.* 2015; Anthony 2016).

The basic premise underlying RBM is that the resilience of coral reefs can be enhanced by addressing the cumulative impacts of local and regional threats (e.g. pollution, sedimentation and overfishing) (Marshall and Schuttenberg 2006; Keller *et al.* 2009; Anthony *et al.* 2015; Anthony 2016). RBM may involve a mix of policy instruments and management actions (e.g. regulation, incentives and education) (Anthony *et al.* 2015, p. 53) relating to, for example, land use controls to improve water quality entering the reef system and spatial planning of marine protected areas, including no-take zones (Anthony *et al.* 2015; Anthony 2016). In terms of the DPSIR framework (Section 1.6), RBM aims to address a range of 'pressures' on the reefs, such as land use in adjacent catchments, coastal development and fisheries.

As an emerging concept, RBM is yet to be addressed in the policy literature. Elsewhere, in the case of coral reefs, there has not been much discussion beyond the suggested need for RBM and strategies to support its implementation.

Internationally, there has been considerable interest in resilience-based approaches to coral reef management. For example, the Coral Triangle Initiative – an intergovernmental effort involving Indonesia, Malaysia, Papua New Guinea, Philippines and Timor-Leste – incorporates resilience principles and multi-issue management (Coral Triangle Initiative Secretariat 2009). Further, the International Union for the Conservation of Nature and Natural Resources (IUCN) has adopted an agenda for action on coral reefs, climate change and resilience, which urges the development of policies to support RBM at national and international levels (Obura and Grimsditch 2009).

#### Case study: The Great Barrier Reef Climate Action Plan 2007-2012

Australia's Great Barrier Reef (GBR) Marine Park is one of the world's pioneers in coral reef management (Day 2016). It is an exemplar of approaches aiming to restore and maintain the resilience of coral reefs in the face of multiple threats, including climate change (Great Barrier Reef Marine Park Authority [GBRMPA] 2009; GBRMPA 2014). In 2007, the Great Barrier Reef Marine Park Authority (GBRMPA)<sup>1</sup> launched the GBR Climate

**Table 14.1: Example of governance approaches and policy instruments to address coral bleaching, marine litter and overfishing**

| Governance approach                                         | Policy instrument                                                                    | Case study                                                                        |

<sup>1</sup> GBRMPA is a federal statutory authority established under the Great Barrier Reef Marine Park Act 1975 with powers to prepare and publish plans and policies relating to the protection and management of the GBR (Commonwealth of Australia 1975).

Change Action Plan 2007-2012, which identified strategies and actions to enhance the reef's resilience and support adaptation by reef-dependent industries and communities (GBRMPA 2007). Once situated in the Council of Australian Governments' National Climate Change Adaptation Framework as a specific action item (Council of Australian Governments 2007), the Action Plan is regarded as the first of its kind, representing a

relevant national and international case study on an adaptation policy cluster applied to the threat of climate change on a world heritage reef system (GBRMPA 2012). Further, the case exemplifies the enabling actors' governance approach; it involves actions for improving understanding of climate change vulnerability and adaptation and raising awareness among reef-dependent communities and industries.

**Table 14.2: Australia's Great Barrier Reef**

| Criterion                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | References                                                                            |
|-----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------|
| <b>Success or failure</b>         | The overall goal of the GBR Climate Change Action Plan 2007-2012 was to maximize the resilience of the GBR to climate change. This involved four objectives: (i) targeted science; (ii) resilient ecosystems; (iii) adaptation of industries and communities; and (iv) reduced climate footprints. The review of the Action Plan highlights the delivery of over 250 individual projects or activities, generation of a diverse range of knowledge resources, including more than 150 reports and papers, and creation of scientific knowledge underpinning new decision-making tools and processes (e.g. developing and refining remote sensing tools that forecast coral bleaching and risks of outbreaks of coral disease). On the other hand, the GBR Outlook Report 2014 recognizes that, despite sound regional-scale management for climate change and other threats, the condition of the reef is still declining. | GBRMPA 2012; GBRMPA 2014                                                              |
| <b>Independence of evaluation</b> | A review of the Action Plan outcomes was undertaken by the GBRMPA (i.e. self-evaluation).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | GBRMPA 2012                                                                           |
| <b>Key actors</b>                 | Alongside the GBRMPA, implementation involved specific stakeholder groups, including traditional owners, tourism operators and the seafood industry, and is believed to have built stronger ongoing relationships across the public, private, community and research sectors.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | Commonwealth of Australia 2016                                                        |
| <b>Baseline</b>                   | A comprehensive vulnerability assessment, including social and economic dimensions, undertaken in 2007 evaluated the threats posed by climate change to the GBR.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | Johnson and Marshall 2007                                                             |
| <b>Time frame</b>                 | The Action Plan was implemented over a five-year period, between 2007 and 2012. The report <i>Climate Change Adaptation: Outcomes from the Great Barrier Reef Climate Change Action Plan 2007-2012</i> was released in 2012.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | GBRMPA 2012                                                                           |
| <b>Constraining factors</b>       | Responding to climate change in the GBR involves cross-sectoral coordination involving several policy sectors and agencies spanning local, state and federal levels of government. Further challenges include compounding multiple spatial and temporal scales, uncertainty, and interlinkages between climate and non-climate drivers (see Chapter 2). Importantly, addressing major threats to the resilience of the reef, such as poor water quality from adjacent catchments and coastal development, are beyond the limits of the GBR Marine Park, therefore outside the jurisdiction of the GBRMPA and the application of the Action Plan.                                                                                                                                                                                                                                                                           | Fidelman, Leitch and Nelson 2013                                                      |
| <b>Enabling factors</b>           | The federal government allocated about A\$9 million to implement the Action Plan. Further, the GBRMPA has provided leadership in managing the GBR since the mid-1970s. It also had capacity and the ability to mobilize additional expertise and partners.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | Commonwealth of Australia 2016                                                        |
| <b>Cost-effectiveness</b>         | Cost-effectiveness information is not available.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                                                                                       |
| <b>Equity</b>                     | The Action Plan did not involve fundamental equity issues. However, commentators point out the need to develop a user pays system for stakeholders impacting the GBR, including those responsible for shipping and port- and land-based activities.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | Morrison and Hughes 2016<br>National Climate Change Adaptation Research Facility 2016 |
| <b>Co-benefits</b>                | Given the inherent nature of RBM, which involves addressing cumulative impacts of local and regional threats, the Action Plan had the potential to benefit existing policies relating to conservation, fisheries and tourism.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | GBRMPA 2012                                                                           |
| <b>Transboundary issues</b>       | Many of the issues in the GBR span multiple administrative and ecological boundaries and involve multiple policy sectors (climate change, agriculture, coastal development and fishing). These pose significant challenges to RBM efforts.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | Fidelman, Leitch and Nelson 2013; GBRMPA 2014                                         |
| <b>Possible improvements</b>      | The Action Plan focused mostly on actions within the GBR Marine Park. Major threats to the resilience of the reef, such as poor water quality from adjacent catchments and coastal development, lie beyond the Marine Park's boundaries. RBM efforts addressing external factors would be highly beneficial; they may require some level of coherence and integration with existing policies targeted at these factors.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                                                                                       |

While RBM does not prevent coral bleaching, it may improve the prospect of recovery following bleaching events. However, without global action to curb carbon emissions, RBM alone is unlikely to be effective, given the limits to the capacity of corals to adapt to warmer ocean waters (Anthony 2016; Hughes *et al.* 2017).

The case of the GBR suggests that RBM will need to navigate complex governance settings involving multiple geographical and jurisdictional scales, levels of social and administrative organization, and policy and resource sectors (Fidelman, Leitch and Nelson 2013). Implementation of RBM may, therefore, involve fostering integration and coherence among existing policies addressing local and regional threats. In this regard, RBM has the potential to enhance overall governance across land–marine jurisdictional boundaries. Expanding the scope of RBM to incorporate the institutional and governance dimensions is critical – as addressing social resilience as part of RBM efforts is – since climate change has significant implications for reef-dependent communities and industries, including their well-being and health (Cinner *et al.* 2016).

#### 14.2.2 Marine litter (regional cooperation policy)

Established in 1974, the Regional Seas Programme is one of the United Nations Environmental Programme's (UNEP) main efforts to address coastal and marine environmental issues. The programme illustrates regional cooperation approaches to coastal and marine management. It focuses on engaging neighbouring countries in regional action plans to address problems in shared marine environments. In many cases, these plans are underpinned by a legal framework in the form of a regional convention and associated protocols on specific issues.

There are currently 18 different Regional Seas Programmes, involving over 140 countries. These include the Mediterranean Action Plan with 22 contracting parties (Albania, Algeria, Bosnia

and Herzegovina, Croatia, Cyprus, Egypt, France, Greece, Israel, Italy, Lebanon, Libya, Malta, Monaco, Montenegro, Morocco, Slovenia, Spain, Syrian Arab Republic, Tunisia, Turkey and the European Union).

Marine litter and debris in the Mediterranean are a well-recognized problem with environmental, economic, health and safety and cultural impacts (e.g. Galgani *et al.* 1995; Stefatos *et al.* 1999; Tomás *et al.* 2002; Campani *et al.* 2013; Pasquini *et al.* 2016). This has prompted the adoption of action plans to reduce pollution.

#### Case study: Regional Plan on Marine Litter Management in the Mediterranean

The densely populated coastline, fisheries, extensive tourism and maritime traffic, including the riverine inputs, have contributed to a continuous increase in marine litter over past decades (e.g. Santos, Friedrich and Barretto; Galgani *et al.* 2014; Rech *et al.* 2014; Unger and Harrison 2016). According to the International Coastal Cleanup Report (Ocean Conservancy 2017), cigarette butts are the most common item found at sea (see also Munari *et al.* 2016), but plastics, especially fragmented consumer products, make up by far the biggest type of marine litter (Li *et al.* 2016).

With the Regional Plan on Marine Litter Management in the Mediterranean (the Plan), the UNEP Mediterranean Action Plan (MAP) was the first Regional Seas Programme and Convention to develop legally binding measures to prevent and reduce the adverse effects of marine litter on marine and coastal environments. Adopted in 2013, the entry into force of the Plan coincided with the update of national action plans of the Mediterranean countries to combat pollution from land-based sources and activities.

The Plan involves some key principles on pollution control and prevention, including the integration of marine litter management into solid waste management and the reduction

**Table 14.3: Regional Plan on Marine Litter Management in the Mediterranean**

| Criterion                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | References                                                                                                                                           |
|-----------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Success or failure</b>         | The Plan contains 42 specific tasks, a timetable, lead authorities, verification indicators, costs and financial sources. The targets set for 2017 have been largely achieved, as many were conditional with "explore and implement to the extent possible". However, many of the aims have passed the explore stage to implementation.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                                                                                                                                                      |
| <b>Independence of evaluation</b> | It is the responsibility of the Contracting Parties to assess the state of marine litter, the impact of marine litter on the marine and coastal environment and human health as well as the socioeconomic aspects of marine litter management. The assessment will be conducted based on common agreed methodologies, national monitoring programmes and surveys.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                                                                                                                                                      |
| <b>Key actors</b>                 | The Plan was adopted by the Contracting Parties to the Convention for the Protection of the Marine Environment and the Coastal Region of the Mediterranean (Barcelona Convention), which includes 21 Mediterranean countries and the European Union (EU).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | UNEP/MAP 2013                                                                                                                                        |
| <b>Baseline</b>                   | An assessment of the status of marine litter in the Mediterranean was undertaken in 2008 and used as a basis for the development of the Plan. EU member states undertook a baseline evaluation of marine litter in accordance with the EU Marine Strategy Framework Directive (MSFD 2008). However, the 2015 marine litter assessment recommended a better definition of baselines and targets. Common baseline values for marine litter indicators (beaches, sea surface, sea floor, microplastics, ingested litter) should be proposed at the level of the entire Mediterranean Sea rather than at the subregional level.                                                                                                                                                                                                                                            | European Parliament and European Council (2008)<br>UNEP/MAP (2016);<br>UNEP/MAP (2015a);<br>UNEP (2016)                                              |
| <b>Time frame</b>                 | The Plan is to be implemented between 2016 and 2025, with the majority of measures to be implemented, where possible, by 2020.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                                                                                                                                                      |
| <b>Constraining factors</b>       | The behaviour of consumers remains a challenge; reducing marine litter will require changes in public perceptions, attitudes and behaviour. Compliance and improved detection and enforcement may prove challenging for effective legislation. Some States have inadequate waste management systems due to a lack of funding and poor governance. Furthermore, there has been a lack of consistency in methods used to tackle the marine litter problem. Responses include regional guidelines and the implementation of pilots such as Fishing-for-Litter and Adopt-a-Beach at a regional level, but there is still room for improvement.                                                                                                                                                                                                                             | UNEP/MAP 2013                                                                                                                                        |
| <b>Enabling factors</b>           | The aims of the Plan are also supported by the EU MSFD and synergistic policies, which include: the European Strategy on Plastic Waste in the Environment, which addresses plastic marine litter and ways to reduce it; a Directive to reduce the use of plastic bags; and the Port Reception Facility Directive, which addresses waste generated by ships at EU ports. The Plan is also supported by the G7 and G20 Action Plans on Marine Litter. Non-governmental organizations (NGOs) have been very active in awareness-raising and education activities. They have made a major contribution to data collection and cleanup operations, mobilizing thousands of volunteers in support of a litter-free Mediterranean. The Plan includes strong provisions on the effective coordination and important role of the various marine litter actors and stakeholders. |                                                                                                                                                      |
| <b>Cost-effectiveness</b>         | Marine litter can cause significant socioeconomic damage, including losses for coastal communities, tourism, shipping and fishing. However, the costs of implementing measures necessary to meet the requirements of the Regional Plan through the National Action Plans are also significant. For example, the cost of coastal and beach cleaning in the EU has been assessed at almost €630 million per year, while the cost to the fishing industry could amount to almost €60 million. UNEP/MAP has carried out work to assist countries with estimating the costs for the Regional Plan and legally binding measures in the region. Furthermore, socioeconomic assessment of the costs and benefits of selected potential new measures has been conducted, including fishing-for-litter, port reception facilities and banning single-use plastic bags.           | Ballance, Ryan and Turpie(2000);<br>Williams <i>et al.</i> (2016); Brouwer <i>et al.</i> (2017);<br>European Commission] (2017);<br>UNEP/MAP (2015b) |
| <b>Equity</b>                     | Both the people and the environment benefit from a reduction in marine litter. Mitigation measures such as deposit return schemes, plastic bag levies and enforcement activities come at a cost, which is unevenly distributed among society.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                                                                                                                                                      |
| <b>Co-benefits</b>                | Co-benefits include increased energy generation from recycling solid waste, and reduced demand for plastic packaging by awareness-raising. Reduced marine litter is also beneficial to marine species, ecosystems and biodiversity.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                                                                                                                                                      |
| <b>Transboundary issues</b>       | Marine litter can be generated in many jurisdictions and migrates across boundaries. Mediterranean marine litter can even enter the sea from the Atlantic through the Strait of Gibraltar or via the Suez Canal, though the larger transboundary origins and effects of Mediterranean marine litter are from Mediterranean coastal States. Marine litter accumulates in hot spot areas. Preliminary work is currently being undertaken at regional level by the UNEP/MAP and other organizations and initiatives to identify where these areas are located.                                                                                                                                                                                                                                                                                                            |                                                                                                                                                      |
| <b>Possible improvements</b>      | The national data on marine litter show inconsistencies between reporting years and between countries with differing reporting systems. Therefore, the variations within the scope of the reporting, different methods of calculation and lack of data validation hinder identification of trends. The 2015 assessment recommended that countries develop more coherent monitoring programmes that include more data collection on sources of marine litter and regular monitoring of microparticles. Stronger enforcement measures need to be introduced to combat illegal discharge or dumping of marine litter, both from land-based sources and at sea, in accordance with national legislation.                                                                                                                                                                   | UNEP/MAP 2014;<br>UNEP/MAP 2016                                                                                                                      |

of litter through a focus on promoting sustainable consumption and production practices. A key component of the Plan is collaboration with the private sector to reduce plastic consumption.

The Plan provides a legally binding set of actions and timelines to reduce marine litter in the Mediterranean. The targets set for 2017 have been largely achieved, as many were conditional with “explore and implement to the extent possible”. However, many of the aims have passed the explore stage to implementation.

Some progress has been made in the use of recycled plastic and in reducing the use of single-use plastic bags. Some Mediterranean countries such as France and Morocco have a total ban on plastic bags. Other countries such as Croatia, Malta and Israel and some municipalities and districts of Spain and Greece have introduced a tax on single-use plastic bags. Tunisia has banned non-biodegradable plastic bags in large-chain supermarkets (Legambiente ONLUS 2017).

On the other hand, the fishing sector has lagged in implementing litter reduction strategies. Although guidelines for the litter scheme have been developed, and the majority of Mediterranean fishermen have indicated a willingness to participate, country surveys indicate that vessels do not have bins or bags on board to store litter items. Fishermen continue to discard unwanted fishing gear into the sea (UNEP 2016). In this regard, a wide range of technologies for marking ownership of fishing gear are available. In fact, Moroccan and EU fisheries laws provide for the marking of both the vessel and the fishing gear carried on board (Food and Agriculture Organization [FAO] 2005), and the Food and Agriculture Organization of the United Nations adopted the Guidelines on Marking Fishing Gear in 2018.

### 14.2.3 Territorial use rights for fishing

An attractive policy for some countries seeking to manage small-scale fisheries is to (re-)enable the traditional users of the resource by allowing (or granting) them exclusive rights to collectively (or occasionally individually – Hauck and Gallardo-Fernández 2013) manage stocks in specific areas themselves. The logic behind these Territorial Use Rights for Fishing programmes (TURFs) (Christy 1992), stem from common property theory and the literature on community or local-scale governance (Ostrom 2002). TURFs are considered to ameliorate overfishing by stimulating resource stewardship among fishers and offering communities various sanctioning mechanisms to hold them accountable (Castilla and Fernández 1998; Wilen, Cancino and Uchida 2012). By engaging the community in the scientific, economic and political decision-making surrounding the setting of limits and the sanctioning of transgressions, TURFs are thought to promote equity and empower and encourage reinvestment in local communities (Villanueva-Poot *et al.* 2017).

TURFs are touted as a good fit for fisheries with relatively sedentary stocks and high exclusionary potential, and are valuable in locations where governance resources are limited (Fernández and Castilla 2005). Hybrid policy designs can extend their applicability though (Barner *et al.* 2015). For

example, more mobile species or fishers can be addressed by establishing broader TURF networks (Aceves-Bueno *et al.* 2017), and some policies combine classic TURFs with marine reserves (so-called TURF-reserve systems – Afflerbach *et al.* 2014; Oyanedel *et al.* 2017). These TURF-reserves serve an important goal of restoring a healthy balance among competing species in the same ecosystem (Loot, Aldana and Navarrete 2005; Oyanedel *et al.* 2017), though studies have found that even classic TURFs may improve the abundance of non-target species through trophic interactions (Gelcich *et al.* 2008; Giacaman-Smith, Neira and Arancibia 2016). Indeed, TURFs could be targeted by private conservation actors (Costello and Kaffine 2017). Lastly, the literature shows that it is important to establish TURFs at an appropriate scale for the target species. TURFs for highly variable species subject to boom-and-bust dynamics should be established at a wide enough geographical scale to allow fishers to maintain their livelihood (Aburto, Stotz and Cundill 2014), while being attentive to interdependencies across individually managed areas due to larval dispersion or governance structures (Garavelli *et al.* 2014; Garavelli *et al.* 2016; Aceves-Bueno *et al.* 2017).

TURFs have proven popular with governments keen to devolve costly management and enforcement functions, but because TURFs can operate based on tradition and without formal establishment, it is unclear exactly how many exist or when they were first introduced (Christy 1992; Afflerbach *et al.* 2014). There are several ways to establish TURFs. In some cases (e.g. in Japan, Palau, Papua New Guinea, Samoa, Solomon Islands and Vanuatu), TURFs are based on centuries-old traditions granting local users exclusive access to nearshore fishing grounds (Le Cornu *et al.* 2017; Nomura *et al.* 2017; Yoshino 2017). In others (e.g. Chile and South Africa), TURFs have been initiated by the government as part of a national or regional co-management framework or were driven by local communities, with the regional or national government providing legal, operational or financial support (Charles 2002; Hauck and Gallardo-Fernández 2013).

A major challenge to TURFs continues to be the persistence of poaching (Andreu-Cazenave, Subida and Fernandez 2017; Oyanedel *et al.* 2018). One option often advocated is to complement local community management with some governmental resources for monitoring, enforcement and centralized dispute resolution (Hauck and Gallardo-Fernández 2013). The literature stresses though that even such co-management arrangements should be context-dependent (Defeo *et al.* 2016). The mix of formal and informal enforcement mechanisms deployed will depend on the biological productivity of the resource (Santis and Chávez 2015), and how well supported the regime is by fishers' social networks (Rosas *et al.* 2014; Crona, Gelcich and Bodin 2017). The importance of the underlying social network to the success of TURFs highlights how demographic changes and intergenerational shifts may ultimately undermine even successful TURFs (Tam *et al.* 2018). Lastly, another major challenge is that the integration of seafood markets continues to put global pressures even on the type of local, small-scale fisheries often governed by TURFs, with varying effects (Crona *et al.* 2015; Castilla *et al.* 2016; Crona *et al.* 2016), which may only be improved by transforming the coastal communities themselves (Saunders *et al.* 2016).

### Case study: Chilean abalone TURFs

Despite some resemblance to abalone, 'Chilean abalone' is a different high-value species of sea snail, known locally as loco, and has been part of the local diet for at least 6,000 years (Reyes 1986; Santoro *et al.* 2017). Historically, the fishery had been open access, but as international 'loco fever' (Meltzoff *et al.* 2002) demanded unsustainable catches, the Government experimented with a series of different policy instruments: seasonal closures from 1981 to 1984; a global national quota from 1985 to 1989; and then total closure from 1989 (Castilla 1995; Castilla and Fernández 1998; González *et al.* 2006; Gelcich *et al.* 2008; Hauck and Gallardo-Fernández 2013). All failed to stem widespread poaching. A 1991 fishing law then outlined area-based rights management schemes that evolved

into the first TURFs being implemented in 1997 (Meltzoff *et al.* 2002). The Government banned loco fishing outside these TURFs and subsidized their establishment through a four-year tax deferment and contributions of up to 75 per cent on any baseline or follow-up assessments (Hauck and Gallardo-Fernández 2013). TURFs subsequently proliferated to other areas and other (relatively sedentary invertebrate) species (Gelcich *et al.* 2017), ultimately encompassing 80 per cent of the Chilean catch and 40 per cent of registered fishers in over 400 TURFs (Fernández and Castilla 2005; González *et al.* 2006; Hauck and Gallardo-Fernández 2013). This case was chosen as a relatively successful attempt to hand over governance to local communities and is a detailed illustration of how scale- and context-dependent different policy instruments are.

**Table 14.4: Chilean fisheries**

| Criterion                         | Description                                                                                                                                                                                                                                                                                                                                                                       | References                                                                                                                                           |
|-----------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Success or failure</b>         | The Chilean Fisheries Department required a policy solution that reduced unsustainable pressure on a highly vulnerable species, returned all fishing access to adjacent community fisheries, and excluded mobile non-resident fishers who were poaching extensively.                                                                                                              | Hauck and Gallardo-Fernández 2013                                                                                                                    |
| <b>Independence of evaluation</b> | Chilean TURFs have been evaluated several times, including by third parties and environmental NGOs.                                                                                                                                                                                                                                                                               | Gonzalez <i>et al.</i> 2006; Earth Justice 2015                                                                                                      |
| <b>Key actors</b>                 | Local communities developed and implemented their TURFs. Processing and marketing sectors were supportive throughout. Most environmental NGOs came late to the process but bought their way in through financial liaisons with individual communities.                                                                                                                            |                                                                                                                                                      |
| <b>Baseline</b>                   | Data to support quantitative baselines and targets were scarce, weak and ad hoc. However, all agreed that loco was severely depleted along much of the coastline and that individual transferable quotas (ITQs) had failed to control extensive illegal fishing.                                                                                                                  | Reyes 1986; Ruano-Chamarro, Subida and Fernández 2017                                                                                                |
| <b>Time frame</b>                 | The first TURFs were established over a two-year transition period and took another decade to spread, but numbers seem to have plateaued since.                                                                                                                                                                                                                                   |                                                                                                                                                      |
| <b>Constraining factors</b>       | Communities with high in-migration and fewer resources for surveillance and enforcement faced greater challenges.                                                                                                                                                                                                                                                                 |                                                                                                                                                      |
| <b>Enabling factors</b>           | The sedentary nature and high market value of the target species was essential to success. Community management relied on communities' cultural and social integrity and the law banning loco fishing outside TURFs.                                                                                                                                                              | Liu <i>et al.</i> 2016                                                                                                                               |
| <b>Cost-effectiveness</b>         | Costs of TURFs to the Government were low, as it transferred monitoring and surveillance costs to the communities, which were willing to undertake them, given the large financial and political returns and some governmental support for their establishment.                                                                                                                   | Gutiérrez <i>et al.</i> 2011                                                                                                                         |
| <b>Equity</b>                     | 'Communities' were self-defined and overlapped more than anticipated, so the first to obtain TURF authorization could marginalize and disempower others. Communities that struggled with adapting to the new system saw increased crime and poaching. Lastly, a 2008 law gave preferential rights to indigenous peoples, which some people considered inequitable.                | Van Holt 2012; Hauck and Gallardo-Fernández 2013                                                                                                     |
| <b>Co-benefits</b>                | Chilean TURFs integrated and empowered local communities, facilitated policy experimentation and provided sustainable ecosystem services and tourism.                                                                                                                                                                                                                             | Hauck and Gallardo-Fernández 2013; Gelcich <i>et al.</i> 2017; Defeo and Castilla 2005, p. 275; de Juan <i>et al.</i> 2015; Biggs <i>et al.</i> 2016 |
| <b>Transboundary issues</b>       | TURFs increased fishing pressure on non-TURF areas and species once the fishing programme adopted by a community was fulfilled for the season or year.                                                                                                                                                                                                                            | Van Holt 2012                                                                                                                                        |
| <b>Possible improvements</b>      | Potential improvements include more stable funding for surveillance and enforcement, stronger integration across scales and better provision for those displaced from the fishery. Innovative business models and municipal conservation areas have been discussed and, in some cases, trialed, but it is too soon to tell whether these will address persistent poaching issues. | González <i>et al.</i> 2006; Gelcich and Donlan 2015; Gelcich <i>et al.</i> 2015                                                                     |

The Chilean abalone TURFs have been regarded as role models (González *et al.* 2006; Gelcich *et al.* 2017). They led to improved catch per unit of effort and sometimes substantial (as much as five-fold) improvements in economic returns. These successes were due to empowering local communities to develop and adopt instruments tailored to their geography and culture. However, illegal fishing continues (Andreu-Cazenave, Subida and Fernandez 2017), in some cases by fishers who abide by rules but fish illegally beyond their own TURFs, undermining ecological outcomes (González *et al.* 2006; Hauck and Gallardo-Fernández 2013; Oyanedel *et al.* 2018). Moreover, the sustainability of economic benefits from the system has seen competitive challenges from other markets and fishery products, and in one region only 5 out of 30 TURFs did well economically (Zuñiga *et al.* 2008). However, despite complaining that TURFs had not always provided significant financial returns and that monitoring costs had been increasing, Chilean fishers were reluctant to relinquish their TURFs, recognizing that they provided benefits across multiple dimensions, including ecological and economic empowerment (Gelcich *et al.* 2017). The transferability of this policy depends on having sedentary species, stable markets, and settled communities with an ability to exclude mobile, non-local fishers.

#### 14.2.4 Individual transferable quotas

ITQs are a type of market-system approach that some governments use to manage fisheries (Selig *et al.* 2016). Typically, ITQs grant their owners exclusive and transferable rights to a given portion of the total allowable catch (TAC) from a fishery each season or year, which can then be bought, sold or leased in an open market. The logic is that because these quotas are individual and not collective, fishers cannot maximize earnings by racing to catch more fish from a common total quota or resource than other license-holders before depletion. Rather, income can only be increased by more strategically catching and marketing their share (for example, through more efficient fishing practices or timing the catch to market opportunities) and through resource stewardship by supporting stock growth so that their fixed percentage applies to a larger total quota. ITQs can thus generate substantial economic returns for society (Hoshino *et al.* 2017), promote economic efficiency by incentivizing reductions in fishing capacity (Blomquist and Waldo 2018) and create an economic incentive for the industry to value stock growth as well as present catch.

ITQs were first introduced on individual fish species in the late 1970s (Chu 2009) by the Netherlands (Hoefnagel and de Vos 2017), Iceland (Chambers and Kokorsch 2017; Kokorsch 2017) and Canada (Rice 2004; Pinkerton 2013; Edinger and Baek 2015; Gibson and Sumaila 2017). They have since been implemented at a range of scales, being first implemented as a national fisheries policy by New Zealand in 1986 (Mace, Sullivan and Cryer 2014) and Iceland in 1990 (Arnason 1993). ITQs have also been proposed as a potential reform option for the European Common Fisheries Policy (Waldo and Paulrud 2012; van Hoof 2013) and for international fisheries management (Pintassilgo and Costa Duarte 2000; Thøgersen *et al.* 2015), but they have not yet seen agreement at these scales.

A comprehensive review in 2009 found that 18 countries managed several hundred different fish stocks with ITQs (Chu 2009). They have been most vigorously adopted in tandem with the privatization of other common assets as a part of broader neoliberalist trends (Pinkerton 2017) – for example, in the United States of America (Porcelli 2017), Australia (Steer and Besley 2016; Emery *et al.* 2017), Argentina (Bertolotti *et al.* 2016) and Chile (Wiff *et al.* 2016), in addition to other countries listed above. Norway (Hannesson 2013; Hannesson 2017), Sweden (Waldo *et al.* 2013; Stage *et al.* 2016; Blomquist and Waldo 2018) and Denmark (Merayo *et al.* 2018) have seen more cautious adoption of ITQs, and other jurisdictions, such as France (Frangoudes and Bellanger 2017), have seen marked opposition. While several developing countries have shown interest in ITQs, they have not seen widespread adoption there, for various reasons that include concerns about economic participation, a backlash against ‘privatizing nature’, or the recognition that ITQs require sound stock assessment and reliable catch monitoring (see below).

Where conditions are favourable, ITQs are recognized as an excellent instrument for promoting economic efficiency in fisheries. However, their mixed record elsewhere has prompted the literature on marine policy and environmental economics to investigate the conditions for policy effectiveness. These conditions relate to scale, technology and capacity, as identified in Section 7.5.

First, ITQs operate best for relatively high-value stocks. Nonetheless, fishers’ high-grading (discarding less valuable species or sizes into the sea to maximize quota value) can still produce negative ecological impacts and can only be deterred by on-board surveillance (as with any quota-based harvesting system). ITQs may have positive ecosystem effects through a variety of indirect mechanisms (Gibbs 2010), but, ultimately, ITQs are a relatively targeted policy instrument that should be well considered.

Second, successful ITQ programmes require strong, independent, scientifically set TACs (Sumaila 2010); otherwise, scientific uncertainty or political interference may erode quota owners’ trust that the quotas are sustainable, restoring incentives to race for fish. For example, Nordic countries offer strong monitoring capabilities and high levels of trust in public institutions (Hannesson 2013; Merayo *et al.* 2018; Blomquist and Waldo 2018).

Third, the economic incentive value of ITQs is especially vulnerable to free-riding illegal, unreported and unregulated (IUU) fishing (Costello *et al.* 2010). Again, strong monitoring, control and surveillance (MCS) is required or target stock status will be undermined.

It should be acknowledged though that ITQs are a policy instrument for promoting economic efficiency in fisheries and not necessarily social equity (Costello, Gains and Lynham 2008; Høst 2015). Issues of social equity can arise during the initial allocation of ITQs or, later, upon their consolidation. Basing allocation on historical usage can exacerbate existing social inequities, particularly if the time frame used favours one group. The New Zealand Government spent considerable sums purchasing ITQs from the initial allocation to satisfy

Maori claims (Deweese 1998). Auctions are an alternative (Bromley 2009), but this may exacerbate pre-existing inequities too if not all parties have sufficient resources to buy in. Even if begun equitably, consolidation of ITQs can concentrate fishing gains and power (Pinkerton and Edwards 2009). Similar to other industries, the economic incentives of ITQs may promote further capitalization and ultimately 'armchair fishing', where corporate owners dissociated from coastal communities absorb harvesting profits. Where processing is also consolidated, small coastal communities may be left to slide into economic depression. To guard against this, many quota management systems limit how great a share each owner may collect. Initiatives such as licence banks may deter such consolidation of fishing opportunities (Edwards and Edwards 2017), but they have not been in place long enough for their social, economic and ecological consequences to be fully evaluated.

Lastly, by reducing the race to fish, ITQs are thought to considerably improve occupational health and safety. Generally, occupational injuries are more prevalent in fisheries than in other professions (Chauvin and Le Bouar 2007; Håvold 2010). But fishers in an ITQ can fill their quota at any time over the season, rather than compete for a total quota with other fishers, so they do not need to venture out in inclement weather, overload their vessels with gear or neglect vessel maintenance (Pfeiffer and Gratz 2016). However, these health benefits only accrue for quota owners; quota lessees or contract workers may still be subjected to pressures to take risks (Windle *et al.* 2008; Emery *et al.* 2014). Occupational safety can also affect how fishers perceive regulation. According to Håvold (2010), while serious fishing accidents justify regulatory frameworks to fishers, minor accidents undermine their impressions. Further research is required to determine how best to ensure the health and safety of those involved in the fishing industry (Lucas *et al.* 2014).

#### **Case study: British Columbia groundfish fishery ITQs**

The groundfish fishery of British Columbia, Canada, is a complex, multi-species commercial capture fishery. Species such as rockfish, hake, Pacific cod and pollock live and feed near the sea bottom, requiring large trawlers to catch them which results in a heavily capitalized and technologically advanced industry. From 1980 to 1995, Canada's Department of Fisheries and Oceans (DFO) managed the fishery through limits on the number of vessel licences and species- and season-specific TACs. However, this drove unsustainable capitalization, as fishers competed to catch as large a share of the quota as possible before it was exhausted (University of British Columbia [UBC] 2017), and several TACs were repeatedly exceeded (Turris 2000). In 1995, DFO closed the fishery and began consultations (see also Koolman *et al.* 2007). While relations between the industry and DFO were adversarial, all agreed that the fishery was heading towards an economic and environmental crash and that policy tweaks would be insufficient (Rice 2004). In 1997, the fishery reopened as an ITQ system. While not the first ITQ management system used in Canadian fisheries (Casey *et al.* 1995; Turris 2000), this was the broadest in terms of number of species governed (eventually over two dozen) and fleet impact (around 130 vessels at the start), and the first to tackle stocks that were already overfished. Ultimately, the ITQ scheme proved successful in improving the fishery's economics (Rice 2004; Branch 2006)

and is thus illustrative of how ITQs can work well under the right conditions.

The ITQ system reversed the decline in status of many key stocks, secured the financial viability of the processing sector and reduced fleet capacity. Moreover, all four major stakeholders eventually supported the programme. DFO Science overcame its distrust of market incentives to reach conservation goals, and DFO Management came to recognize that making industry management partners somewhat relieved budgetary pressures associated with monitoring and enforcement. The processing sector enjoyed greater market stability and value, and licence holders (even those who ended up leaving the fishery) recognized alternatives as untenable and the market as ultimately safer and more stable. The British Columbia groundfish case is, therefore, instructive as a model for rationalizing a complex, larger-scale, multi-species and heavily capitalized fishery. Indeed, it refutes common wisdom that cooperation requires few parties (there are at least 30 independent players in the fishery) or should be localized (the fleet operates along the whole British Columbia coastline). Still, it is not a strategy for small-scale, livelihood-oriented fisheries and is usually expensive to set up, if not maintain. This case's success depended on strong science and management support, high product value and a reasonably strong economy. It should also be noted that, even if financially sustainable, the policy may not be ecologically sustainable, though more research is required.

Table 14.5: British Columbia fisheries

| Criterion                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | References                                                                       |
|-----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------|
| <b>Success or failure</b>         | Two main policy goals were established by the formal Groundfish Advisory Committee (GAC): stopping the decline of many key stocks and securing financial viability for the processing sector. A subsidiary goal was to downsize fleet capacity to support positive revenue for each participant. These goals were met.                                                                                                                                                                                                                | Turris 2000                                                                      |
| <b>Independence of evaluation</b> | DFO evaluates all fisheries management plans periodically, and more detailed evaluations of several aspects of the ITQ have been conducted by external academics.                                                                                                                                                                                                                                                                                                                                                                     | Fisheries and Oceans Canada 2017; Wallace <i>et al.</i> 2015                     |
| <b>Key actors</b>                 | The policy itself was developed behind closed doors by a subset of the GAC, which brought together all four main interests: harvesting, processing, science and management.                                                                                                                                                                                                                                                                                                                                                           | Rice 2004                                                                        |
| <b>Baseline</b>                   | Baselines were based on historical records of stock status, and plant operating costs and revenues going back at least 15 years.                                                                                                                                                                                                                                                                                                                                                                                                      | Richards 1994; Ainsworth <i>et al.</i> 2008                                      |
| <b>Time frame</b>                 | The ITQ was successfully implemented within one year. Rockfish prices increased six-fold in six months, principally due to better matching of supply and demand. The number of vessels nearly halved within 18 months.                                                                                                                                                                                                                                                                                                                | UBC 2017                                                                         |
| <b>Constraining factors</b>       | Funding to establish the allocations and monitoring and information systems and to buy out those willing to leave the fishery until fleet capacity adapted was the major constraining factor.                                                                                                                                                                                                                                                                                                                                         |                                                                                  |
| <b>Enabling factors</b>           | An important enabling factor was the economic status of British Columbia at the time, which enabled fishers who left the fishery to find alternative work.                                                                                                                                                                                                                                                                                                                                                                            |                                                                                  |
| <b>Cost-effectiveness</b>         | Setting up the ITQ system involved large upfront costs, especially from licence buy-outs. DFO had accurate estimates of these costs, though no ex-post cost-effectiveness analysis was done, since the only alternatives recognized were fishery closure or depletion.                                                                                                                                                                                                                                                                |                                                                                  |
| <b>Equity</b>                     | The policy eliminated both especially large vessels, which could no longer fill their holds, and smaller vessels, which could not bear the observer costs, from the fleet. While there was a licence buyback programme, no provision for employment transition was offered. More consistent supply also made for more consistent work for fish-cutters, mostly women. Overall, although the extension of the fishing season increased industry costs, these were largely in the form of wages, which may have improved social equity. | Stainsby 1994; Matulich, Mittelhammer and Reberte 1996; Dolan <i>et al.</i> 2005 |
| <b>Co-benefits</b>                | A major co-benefit was an improvement in workplace safety and occupational health. Whereas, under the previous regime, fishers might go out in hazardous conditions just because the fishery happened to be open, to catch as much as possible before the full quota was taken, now they could manage their own share over time, going out when it was safer to do so.                                                                                                                                                                | Dolan <i>et al.</i> 2005                                                         |
| <b>Transboundary issues</b>       | Most international transboundary issues (with the United States) related not to groundfish but salmon, Pacific halibut or hake.                                                                                                                                                                                                                                                                                                                                                                                                       | Ianson and Flostrand 2010                                                        |
| <b>Possible improvements</b>      | Though financially sustainable, in the mid-2000s environmental NGOs protested about the ecological sustainability of bottom-trawling on marine habitats. They engaged the fishery industry and proposed by-catch limits to DFO that relied on the same quota and observer system for implementation.                                                                                                                                                                                                                                  | Branch 2009; Wallace <i>et al.</i> 2015                                          |

### 14.2.5 Command and control approaches for the high seas

Command and control policies are a type of norm or policy arrangement that regulates activity by combining legal instruments detailing rules and obligations and 'control' mechanisms, such as sanctions, penalties or fees, that deter actors from infringing those rules. It is associated with the concept of legalization (Abbot *et al.* 2000) and includes three main characteristics: obligation, precision and delegation. Obligation means that actors (state and non-state) are legally bound by a set of rules. Precision means that rules unambiguously define the conduct required by a given actor

or set of actors; and delegation means that third parties are granted authority to implement the rules, monitor compliance and apply sanctions for non-compliance.

Despite not being command and control, as defined above, many of the United Nations conventions and resolutions are translated, at the national level, into command and control approaches. Examples are the 1982 United Nations Convention on the Law of the Sea, which sets out the legal framework within which all activities in the oceans must be undertaken, and United Nations General Assembly (UNGA) Resolution 61/105 (UNGA 2006) on vulnerable marine ecosystems.

The United Nations Convention on the Law of the Sea contains a comprehensive set of rules for regulating the use and management of ocean spaces and their resources. It includes provisions on:

- i. the extent and delimitation of the maritime zones;
- ii. coastal States' sovereignty, sovereign rights and jurisdiction in the areas under national jurisdiction;
- iii. flag States' rights and duties;
- iv. the protection and preservation of the marine environment;
- v. the conservation and management of living marine resources;
- vi. the legal status of resources on the seabed, ocean floor and subsoil beyond the limits of national jurisdiction and activities therein; and
- vii. marine scientific research; development and transfer of marine technology; and the settlement of disputes.

Many fish stocks have been overexploited at an unprecedented rate (Levin *et al.* 2016), particularly due to the effectiveness and intensification of modern vessels and technology to explore the oceans, and the difficulties of monitoring, control and surveillance (FAO 2016). Several rules have been implemented over the years, from local to global (Bigagli 2016), under the oceans' complex regime (Keohane and Nye 1977; Keohane and Victor 2011), to regulate resource use and protect biodiversity. However, the lack of enforcement mechanisms is worrisome, as only a fraction of treaties applying to oceans have specific enforcement mechanisms (Al-Abdulrazzak *et al.* 2017).

Within the DPSIR framework (Section 1.6), command and control policy instruments mostly address 'pressures' (e.g. fishing, mining and pollution). Command and control approaches applied to the high seas have been implemented at a regional and sectoral level, with multiple authorities managing parts of the same regions, and extensive areas without governance arrangements. Further, attempts to coordinate activities, mitigate conflicts, address cumulative impacts or facilitate communication have been inadequate (Ban *et al.* 2014). One of the reasons highlighted by Al-Abdulrazzak *et al.* (2017) for such a state of affairs is that States with small environmental budgets may be unable to participate effectively in the many distinct agreements. Further, the lack of coordination among these treaties risks turning the years of government negotiations into 'empty treaties' with no accomplishments. Ultimately, the success of command and control policy depends on the political will of national governments (Englander *et al.* 2014).

#### **Case study: UNGA Resolution on Vulnerable Marine Ecosystems**

Within the context of sustainable fisheries, UNGA adopted Resolution 61/105 (UNGA 2006), which calls on regional fisheries management organizations (RFMOs) and States to adopt and implement measures, in accordance with the precautionary approach, ecosystem approaches and international law, as a matter of priority. According to paragraph 83 of the Resolution, regional fisheries management organizations or arrangements (RFMO/As) with the competence to regulate bottom fisheries are called on to adopt and implement measures, such as:

- ❖ "Conduct impact assessments of individual high seas bottom fisheries to ensure that 'significant' adverse impacts on vulnerable marine ecosystems (VMEs) would be prevented or else prohibit bottom fishing;
- ❖ Close areas of the high seas to bottom fishing where VMEs are known or likely to occur unless bottom fisheries can be managed in these areas to prevent significant adverse impacts on VMEs;
- ❖ Ensure the long-term sustainability of deep-sea fish stocks; and
- ❖ Require bottom-fishing vessels to move out of an area of the high seas where 'unexpected' encounters with VMEs occur" (UNGA 2004).

The remoteness and extent of the high seas provide real challenges to law enforcement, and to command and control approaches more generally. Alternatives to these approaches are less likely to succeed, given the low social coherence among global actors participating in high-seas fisheries. Still, UNGA Resolution 61/105 (UNGA 2006) on VMEs has begun a process of addressing the problem and has engaged different stakeholders to protect marine ecosystems. It triggered subsequent actions, including further policy developments regarding implementation, and action at the RFMO level. Major gaps include shortcomings in the design and capacities of RFMOs and the political will of countries to enforce regulations. If fully implemented, the Resolution will provide a good basis for protecting VMEs from significant adverse impacts resulting from bottom fishing and ensuring the long-term sustainability of deep-sea fish stocks.

Table 14.6: International cooperation resolutions

| Criterion                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | References             |
|-----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------|
| <b>Success of failure</b>         | Where VMEs have been identified and fishing vessels with bottom-contacting gears have been effectively excluded, the outcome of no further damage of the VMEs from fishing is likely to be occurring.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | Rogers and Gianni 2010 |
| <b>Independence of evaluation</b> | UNGA adopts resolutions on sustainable fisheries annually. As part of this process, following the adoption of Resolution 61/105 in 2006 (UNGA 2006), UNGA conducted dedicated reviews of the implementation of the provisions of the Resolution, as well as subsequent resolutions, addressing the impacts of bottom fishing on VMEs and the long-term sustainability of deep-sea fish stocks in 2008, 2011, 2014 and 2016. Each of these reviews resulted in the adoption of additional provisions in UNGA Resolutions 63/112, 66/68, 69/109 and 71/123. A further review is planned for 2020. In 2014 and 2016, the reviews were preceded by two-day informal multi-stakeholder workshops. In addition, bottom fishing is also addressed in the context of the Review Conference on the United Nations Fish Stocks Agreement, which was held in 2006 and resumed in 2010 and 2016. |                        |
| <b>Key actors</b>                 | Other than States, FAO and RFMO/As are the principal bodies involved in the implementation of the provisions of Resolution 61/105 et seq. Discussions regarding the implementation of the resolutions have involved representatives of these intergovernmental organizations, as well as representatives of environmental NGOs, the fishing industry and academia.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                        |
| <b>Baseline</b>                   | The Resolution was based on historical records of stock status and fish-processing plants' operating costs and revenues. Both sources are reliable for the last 15 years.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | FAO (2009; FAO 2010)   |
| <b>Time frame</b>                 | It took two years for the VME identification criteria to be developed by FAO, and another two years for some RFMOs to identify their VMEs. Most RFMOs identified their VMEs within the time frame established in the Resolution.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                        |
| <b>Constraining factors</b>       | The capacity of some RFMOs to identify VMEs and develop protective measures is limited – for example, in parts of the Pacific and Indian oceans.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                        |
| <b>Enabling factors</b>           | Protecting biodiversity in the high seas had been part of UNGA's agenda for several years, and it had accordingly adopted a series of pre-resolutions (e.g. Resolution 59/25). Improved technologies for distant-water surveillance, such as vessel monitoring systems and satellite tracking, have made the detection of illegal fishing more feasible. Video technologies also allow the automated and less costly monitoring of on-board operations. Increased scientific study of deep-sea habitats and the use of on-board observers also seem to be important factors.                                                                                                                                                                                                                                                                                                         | UNGA 2004              |
| <b>Cost-effectiveness</b>         | No information on cost-effectiveness is available.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                        |
| <b>Equity</b>                     | The Resolution affects national and corporate interests large enough to have the technology to fish the high seas. However, it may entail a uniform burden on countries with different capacity to comply.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                        |
| <b>Co-benefits</b>                | There is potential for improved fishing practices beyond VMEs; more active collaboration between RFMOs and other authorities (seabed mining, shipping and the Convention on Biodiversity) to coordinate conservation efforts; and increased participation of scientific experts in RFMOs and national assessment and advisory bodies.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                        |
| <b>Transboundary issues</b>       | The Resolution applies to multiple jurisdictions and overlaps with other international efforts such as the Convention for Biological Diversity's (CBD) Ecologically or Biologically Significant Marine Areas. In this regard, CBD and FAO cooperate to harmonize the outcomes of these efforts. Cooperation between Canada and the United States, where federal fisheries management agencies identify VMEs or ecologically or biologically significant areas (EBSAs) that straddle national boundaries, illustrates such bilateral efforts. Regional seas conventions also engage in identifying transboundary and/or high-seas EBSAs and can be considered a transboundary issue within a multilateral effort.                                                                                                                                                                     |                        |
| <b>Possible improvements</b>      | Disseminating this type of policy at the national level would be important, given the role of the Resolution as a springboard for more meaningful negotiations in the context of the Marine Biological Diversity of Areas Beyond National Jurisdiction (BBNJ) process. The Secretary-General, in his 2016 report (A/71/351), concluded that "[o]verall, while a number of actions have been taken, implementation of resolutions 64/72 and 66/68 on a global scale continues to be uneven and further efforts are needed (UNGA 2016). Unless timely actions are taken by all the stakeholders concerned, overfishing of deep-sea species is likely to continue and some VMEs will not be adequately protected from significant adverse impacts".                                                                                                                                     |                        |

## 14.3 Indicators

The case studies analysed above provided insights into challenges and opportunities for policy design and implementation in responding to key contemporary threats to the oceans. Further insights may be gained by examining policy-sensitive indicators relating to these threats.

### 14.3.1 Indicator 1: Coverage of marine protected areas

Marine protected areas (MPAs) are defined as “a clearly defined geographical space, recognised, dedicated and managed, through legal or other effective means, to achieve the long-term conservation of nature with associated ecosystem services and cultural values” (Dudley 2008). The coverage of MPAs is calculated for each country using the World Database on Protected Areas, managed by the UNEP World Conservation Monitoring Centre (WCMC) and IUCN. It is expressed as the percentage of MPAs within waters under national jurisdictions.

Current projections indicate that 7.3 per cent of the world's oceans have been designed as MPAs (UNEP-WCMC and IUCN 2018). Sala *et al.* (2018) argue that these projections are overestimated, given that they include areas that are yet to exclude significant extractive activities. Their projection indicates that the actual coverage of MPAs is 3.6 per cent, and only 2 per cent is being strongly or fully protected (Sala *et al.* 2018). In any case, while MPA coverage has been increasing (Figure 14.1), additional efforts are required to meet the internationally agreed targets.

#### Policy relevance

MPAs and other area-based management tools have been promoted through international conventions and agreements, including the Convention on Biological Diversity (CBD) and policy instruments, such as the annual UNGA resolutions and the Sustainable Development Goals (SDGs).<sup>2</sup> Protected areas are also essential in achieving the CBD Aichi Targets 5

and 12, which aim to prevent or reduce the rate of habitat and species loss, respectively. Further, some coastal MPAs are also recognized as wetlands of international importance under the Ramsar Convention.

#### Casual relation

MPAs are a key conservation and management tool, particularly in the context of biodiversity and fisheries. They are part of area-based approaches, such as integrated coastal zone management and marine spatial planning. MPAs have the potential to address several pressures relating to marine biodiversity, including overfishing and habitat destruction. They help protect areas of ecological importance and ensure the provision of ecosystem services (e.g. fisheries, coastal protection, tourism and recreation) (Organisation for Economic Co-operation and Development [OECD] 2017), with important implications for human health and well-being (Kareiva and Mavrić 2012). Further, MPAs have increasingly been promoted as a strategy to enhance the resilience of ecosystems to climate change (McLeod *et al.* 2009; Simard *et al.* 2016). Accordingly, the MPAs indicator addresses multiple issues identified in Chapter 7 of this report, particularly those relating to fisheries and climate change. Chapter 7 also recommends that, in the case of coral bleaching, reef-owning nations should consider taking immediate action (including establishing MPAs) to protect all known coral reef habitat from any non-subsistence uses (see Section 7.5.2).

#### Other influencing factors

National and subnational efforts are required to enhance the design and implementation of MPAs to ensure they meet their intended objectives. Evidence suggests that many nations are yet to meet key challenges such as:

- i. strategically designing MPAs to maximize environmental and socioeconomic benefits;
- ii. preparing and implementing adequate management plans;
- iii. establishing robust monitoring and reporting frameworks;
- iv. ensuring compliance and enforcement;
- v. mobilizing finance to enable sustainable management; and
- vi. embedding MPAs in policy mixes to address multiple pressures (OECD 2017).

#### Caveats

MPAs vary according to their management objective; they range from wholly biodiversity-focused MPAs to those incorporating human use (Dudley 2008). Accordingly, their contribution to achieving ocean conservation targets may vary. Further, the coverage of MPAs alone does not indicate that such areas are effectively and equitably managed. Efforts to develop methods for evaluating the effectiveness of MPAs are, therefore, critical. Examples of these methods include Protected Area Management Effectiveness and the Management Effectiveness Tracking Tool (Stolton *et al.* 2007; Coad *et al.* 2015).

### 14.3.2 Indicator 2: Beach litter assessment

Being relatively simple and cost-effective to monitor compared to other forms of marine litter (see Section 7.5.3), beach litter surveys are a common assessment method (e.g. Gabrielides *et al.* 1991; Madzena and Lasiak 1997; Willoughby *et al.* 1997; Velander and Mocogni 1999; Ballance, Ryan and Turpie 2000; Santos, Friedrich and Barretto 2005; Jayasiri *et al.* 2013; Hong

Figure 14.1: Coverage of Marine Protected Areas

Source: UNEP-WCMC and IUCN (2018)

<sup>2</sup> CBD Aichi Target 11 states: “By 2020, at least... 10 per cent of coastal and marine areas, especially areas of particular importance for biodiversity and ecosystem services, are conserved through... systems of protected areas...”. SDG 14.5 states: “By 2020, conserve at least 10 per cent of coastal and marine areas, consistent with national and international law and based on the best available scientific information”.

*et al.* 2014; Munari *et al.* 2016; Williams *et al.* 2016; Botero *et al.* 2017; Brouwer *et al.* 2017; Nelms *et al.* 2017; Rangel-Buitrago *et al.* 2017; Syakti *et al.* 2017). The key purpose is to assess trends in the volume, composition and spatial and temporal distribution of marine litter washed ashore or deposited on coastlines. The scope of the survey is limited to what is defined as a beach, which precludes very shallow tidal mudflat areas that may be many kilometres wide at low tide (Cheshire *et al.* 2009). The Northwest Pacific Action Plan (NOWPAP) and Convention for the Protection of the Marine Environment of the North-East Atlantic (OSPAR) selection criteria specify that sites should not be in close proximity to rivers, harbours or ports (NOWPAP 2008; OSPAR 2007). Buried litter is usually not sampled, though it may be a considerable proportion of beach litter.

### Policy relevance

Although 'floating plastic debris density' was chosen as one of the indicators for SDG target 14.1: "By 2025, prevent and significantly reduce marine pollution of all kinds, in particular from land-based activities, including marine debris and nutrient pollution", it has been argued by many that beach litter should complement it. Many of the Regional Seas Conventions and Action Plans have agreed on beach litter as their core indicator for marine litter.

Various protocols outline the basic structure of the survey, the analysis of sampling units, the frequency and timing of surveys, the systems used for litter classification and the underpinning framework for facilitation and management of logistics. The data on beach litter generated through such standardized methodology can be useful for setting and achieving policy targets.

### Causal relation

Beach litter originates from various sources; beach cleanup and monitoring programmes (such as Clean up Australia and the United Kingdom's Marine Conservation Society campaigns) have defined 'item indicators' to address the sources of litter. Some beaches will better indicate specific sources of litter than others due to their location (remote beaches or urban beaches tracking ship and urban pollution, respectively). Many studies dedicated to local beaches surveys and litter collection provide information on litter and tourism (UNEP/MAP 2015c). However, seasonal variations are common. While beach users were the main source of summer debris, litter in the tourist low season was primarily attributed to drainage and outfall systems. Other sources include floating litter washed ashore, coastal urbanization, wind-borne litter and illegal dumping. Changes in oceanographic (e.g. currents) and weather (e.g. storms) conditions may affect quantities of beach litter washed ashore.

### Other influencing factors

The benefits of using beach litter as an indicator include the possibility to include citizen science (the participation of non-professional scientists in a scientific project). Because the technique is relatively simple, volunteers are able to participate in the quantification and monitoring of seasonal and site-specific beach litter (Rosevelt *et al.* 2013; van der Velde *et al.* 2017; Vincent *et al.* 2017). Furthermore, beach surveys provide a mechanism for education and building community understanding and awareness. For example, public participation in the cleaning campaigns is strong in the Mediterranean Sea. Comprehensive and regular surveys of marine litter on beaches have been made in many areas, often over a number of years, by various NGOs in the region (UNEP/MAP 2015c).

### Caveats

It has been repeatedly emphasized that there is a need to develop and implement a standardized marine litter sampling protocol. A standardized method would allow quantification and understanding of the amount of litter within our seas and oceans through long-term, broad-scale, comparative studies (Cheshire *et al.* 2009; Besley *et al.* 2017). The lack of standardization and compatibility between methods used and results obtained in various bottom-up projects has made it difficult to compare data from different regions and to make an overall assessment of marine litter pollution for the entire region. Some regions have recently adopted a regional framework, such as the Regional Plan on Marine Litter Management in the Mediterranean, to coordinate and harmonize monitoring. Furthermore, it would help to make the categories for reporting compatible across different survey types (beaches, sea surface, sea floor), so that outcomes are comparable.

It can be difficult to draw conclusions regarding the overall increase or decrease of beach litter if variables change every year, including the number of volunteers participating in beach cleanups. More fundamentally, beach surveys may not relate to true marine pollution; because they may be affected by weather, the stranded debris may not necessarily provide a good indicator of changes in overall abundance (UNEP/MAP 2015c).

### 14.3.3 Indicator 3: Number of Vulnerable Marine Ecosystems identified by Regional Fisheries Management Organizations and closed to fishing or otherwise protected (1,000/934/934)

This indicator measures the number of marine ecosystems that have been identified as vulnerable to impacts from fishing activities and are protected by RFMOs (**Figure 14.2**). This indicator serves as a complement to the stock status indicators (e.g. references to FAO State of World Fisheries and Aquaculture (SOFIA) reports) used in Chapter 7. It relates to a debate in wider policy literature on how to protect biodiversity. Although some approaches prefer sectoral regulation, such as on fisheries, mining or shipping, others (such as that underlying this indicator) advocate complete protection of biodiversity and habitats from all threats regardless of sector. VMEs are identified by an internationally agreed process that can be found in paragraph 42 of the International Guidelines for the Management of Deep-sea Fisheries in the High Seas (FAO 2009) and entail a management response that is generally embedded in the management process of RFMOs.

#### Policy relevance

As described in Section 14.2.5, 14.2.6, the concept of a VME gained momentum following UNGA Resolution 61/105. It stems from the *Rio +20* commitment to enhance actions to protect VMEs, such as impact assessments, but is most recently established in SDG 14 on oceans, particularly targets 14.2 and 14.4. VME protection also appears in CBD Aichi Target 6.

#### Causal relation

UNGA has identified a number of marine habitats with vulnerable ecosystem features (**Figure 14.2**), including coastal lagoons, mangroves, estuaries, wetlands, seagrass beds and coral reefs, but also areas further from shore and sometimes beyond national jurisdiction, such as spawning and nursery grounds, cold-water corals, seamounts, various features associated with polar regions, hydrothermal vents, deep-sea trenches, submarine canyons and oceanic ridges (UNGA 2004). Here we concentrate on the identification and protection of VMEs by RFMOs, showing the areas of coverage through maps, as numbers were not available.

RFMOs have been required to protect VMEs since 2008, with specific requirements laid out under UNGA Resolutions 59/25, 61/105 and 64/72. VME protection typically consists of banning or otherwise restricting bottom-trawling in VMEs. Bottom-trawling consists of vessels dragging nets along or near the bottom of the sea; it is considered especially destructive because it is both indiscriminate, including considerable by-catch beyond the target species, and operates at the same part of the water column as many of the most vulnerable species and much oceanic habitat. RFMOs are expected to help identify VMEs within their regulatory areas, which are often beyond areas of national jurisdiction, and protect them against destructive practices.

#### Other influencing factors

Despite some early adoption, RFMO implementation has been variable. While recently established RFMOs such as the South Pacific (SP) RFMO and the Southern Indian Ocean Fisheries Agreement (SIOFA) expand the marine area beyond national jurisdiction subjected to regulatory opportunities, they may not yet provide adequate stock assessment and leave some

VMEs open to bottom-trawling unless environmental impact assessments (see Section 11.3.2) highlight that further restrictions are necessary (Currie 2016). Other RFMOs, such as the North East Atlantic Fisheries Commission (NEAFC), the Northwest Atlantic Fisheries Organization (NAFO) and the South East Atlantic Fisheries Organisation (SEAFO), have closed substantial areas that are likely to contain VMEs, and the Convention on the Conservation of Antarctic Marine Living Resources (CCAMLR) has banned bottom-trawling in some areas. NAFO has identified 20 areas as being vulnerable to bottom-trawling and subsequently closed them (**Figure 14.3**). The General Fisheries Commission for the Mediterranean (GFCM) lags behind other RFMOs in fulfilling these obligations. GFCM measures to protect VMEs are limited to three fisheries restricted areas (FRAs) and a prohibition on trawling below 1,000 metres. Most VMEs in the Mediterranean are, therefore, entirely unprotected (Oceana 2016).

#### Caveats

Banning destructive fishing practices in VMEs may not guarantee their preservation. Lost driftnets, marine litter, ocean acidification and eutrophication can all affect VMEs, even if they are protected from destructive fishing practices. Further, relying on protected VMEs as an indicator potentially disregards important, unprotected VMEs. However, compared to terrestrial ecosystems, data on marine biodiversity remain limited (Martin *et al.* 2015). IUCN's Red List of Ecosystems (IUCN 2017) provides a third-party attempt to catalogue ecosystems, including marine ecosystems, that are most vulnerable. The goal is to have all ecosystems assessed by 2025. This and further indicators should be developed.

Figure 14.2: Areas of predicted deep-sea vulnerable marine ecosystems

Note: Areas in red illustrate the extent of deep-sea (>200m) bottom-trawling on VMEs predicted from published habitat suitability models and binary predicted presence maps.

Source: Pham et al. 2014

Figure 14.3: Bottom-trawling and closed VMEs from 2006 to 2016

Note: Green-filled areas are bottom-fishing areas, and red-filled areas are VME closed areas. Diagonally shaded areas represent the regulatory areas of key regional fisheries bodies.

Source: FAO (2017).

## 14.4 Discussion and conclusions

Diverse governance approaches and policy instruments have been used in response to the impacts of climate change, pollution and overfishing on the ocean. These approaches and instruments have achieved different levels of success. For example, while RBM has only had a limited impact in minimizing coral bleaching in the GBR, ITQs reversed the decline in status of many key fish stocks and secured the financial viability of the processing sector in British Columbia.

The cases examined in this chapter provide useful insights into policy design and implementation. For example, the success of the Chilean abalone TURF is due to meaningful community involvement in developing and implementing a range of management arrangements. In the case of the Regional Plan on Marine Litter Management in the Mediterranean, stakeholder collaboration to reduce plastic consumption is a key component of the Plan. However, more diverse stakeholders were only included in the VME process after the UNGA Resolution was adopted. Common to most of the cases was the involvement of relevant stakeholders, including resource users, businesses, experts, environmental NGOs and government, at some point in the policy process.

Another feature common to most of the cases was the use of baseline information. For example, a comprehensive assessment of the threat posed by climate change to the GBR informed the RBM initiative; an assessment of the status of marine litter in the Mediterranean was used as a basis for the development of the Regional Plan; and historical records of stock status and plant operating costs and revenues supported the establishment of the ITQs in British Columbia. In addition to informing policy design, baselines establish the preconditions against which progress towards achieving desired goals can be measured, and additional interventions to improve implementation can be made. For example, in the case of UNGA Resolution 61/105 concerning VMEs, additional provisions were adopted (in Resolution 64/72) to

improve implementation once it was recognized that adoption was not proceeding rapidly enough. Despite its importance, baseline information is not always reliable or available; though this should not prevent policy interventions. In the case of the Chilean abalone TURF, existing baseline data were weak and ad hoc. TURFs were established based on common knowledge of the severe levels of stock depletion and failed attempts to control extensive illegal fishing using ITQs.

Another important insight from the case studies is that policy effectiveness is context-dependent. That is, a policy is more likely to prove effective where favourable conditions exist. These enabling factors include leadership, expertise, funding and stakeholder support. For example, the relative implementation success of UNGA Resolution 61/105 in the North Atlantic is associated with existing scientific support and strong surveillance and enforcement capabilities. Conversely, conditions for implementing UNGA Resolution 61/105 are still to be developed in parts of the Pacific and Indian oceans. Strong governance capabilities have been key to successful ITQ implementation. Further, policy interventions need to be tailored to the circumstances where they apply. For instance, the success of Chilean abalone TURFs is attributed to management arrangements being adapted according to geographical and community characteristics.

Last, there is an apparent lack of explicit consideration of the policies and indicators examined regarding human health and well-being. For example, the establishment of MPAs which might restrict access rights of traditional coastal populations may have negative impacts on their livelihood, food security and health. Likewise, the impact of increasingly warmer oceans may result in more frequent phytoplankton blooms, some of which relate to shellfish and fish poisoning and conditions conducive to cholera outbreaks (Cinner *et al.* 2016). These and other health and well-being implications need to be considered as part of ocean policies, if the goal of a 'healthy planet, healthy people' is to be achieved.

# Chapter 15

## Land and Soil Policy

**Coordinating Lead Authors:** Klaus Jacob (Freie universität Berlin), Peter King (Institute for Global Environmental Strategies), Diana Mangalagiu (University of Oxford and Neoma Business School)

**Lead Authors:** Pandi Zdruli (Mediterranean Agronomic Institute of Bari [CIHEAM-Bari]), Katharina Helming (Leibniz Centre for Agricultural Landscape Research [ZALF]), Andrew Onwuemele (Nigerian Institute of Social and Economic Research [NISER]), Leila Zamani (Department of Environment of the Islamic Republic of Iran)

**GEO Fellows:** Darshini Ravindranath (University College London), Hung Vo (Harvard University)

# Executive summary

**Land protection policies differ between regions and countries from barely existent to well defined** (*established but incomplete*). However, their implementation has many shortcomings. Often, national policies addressing socioeconomic development (e.g. economic incentives for agricultural, bioenergy and urban development) have overlooked land degradation side effects. As long as economic growth is not decoupled from environmental degradation, sustainable use and management of land requires policy frameworks that better integrate land management governance across sectors, especially in developing countries. This chapter analyses the effectiveness of policies and policy approaches addressing land quality dynamics in five case studies having different socioeconomic and physical contexts and management approaches. The intention is to draw messages for policy and decision makers when dealing with complex land issues in a context of competing interests and scarcity of resources. {15.4}

**Land degradation is likely to be aggravated as long as effective land and soil management policy frameworks are not established at national and international levels** (*established but incomplete*). Global trade and land acquisitions, including land grabbing, have direct consequences on the livelihoods of local people and international food trade markets. {15.1, 15.2}

**Land degradation and lack of policy action may accelerate migration in some regions** (*well established*). The Intergovernmental Science-Policy Platform on Biodiversity and Ecosystem Services notes "by 2050, an estimated 4 billion people will live in the drylands and until then it is likely that land degradation and climate change will have forced 50-700 million people to migrate". This will result in increased hardship for most areas in Africa, South Asia, the Middle East, and North Africa that will be impacted by rapid population growth, low per capita gross domestic product (GDP), limited options for agricultural expansion, increased water stress and high biodiversity losses. {15.1}

**Land degradation and desertification could be prevented within the context of local social, economic and political conditions** (*well established*). Sustainable land management practices can reverse even severe desertification processes. But the implementation of such practices necessitates policy frameworks that support the involvement and compensation of local people with public money or through public-private partnerships, including direct financing from the private sector alone. Such incentives, however, are country specific and depend on financial resources available. {15.2.1}

**Land is a key source of ecosystem functions and services. Consequently, land-use change is the major direct driver of the loss of ecosystems services and biodiversity** (*well established*). In 2017, the estimated global ecosystem services losses due to land degradation were between US\$6.3 trillion and US\$10.6 trillion per year. This estimated loss is equal to 10-17 per cent of global GDP (US\$63 trillion in 2010), while halting and reversing current trends of land degradation could

generate up to US\$1.4 trillion per year in economic benefits if sustainable land management policies would be implemented. {15.2; 15.2.2}

**Land policy frameworks to tackle risk to human health from soil contamination are scattered and incomplete** (*established but incomplete*). The 'polluter pays' principle is not widely applied and the cost of remediation is very high, preventing its implementation even in developed countries. Lack of knowledge and data gaps further hinder its implementation. Hence a reconsideration of that principle, or otherwise a strong commitment from the government (local, regional, national) to act, is needed to safeguard public health. The contamination of land with heavy metals, pesticides, organic pollutants and other toxic substances severely threatens humans as they are taken up by plants used for food. These effects are even more severe in developing countries that are faced with lack of financial resources and expertise to tackle soil pollution. {15.2.3, 15.2.4}

**Sustainable land management is a major instrument for climate change mitigation because it improves carbon sequestration in the soil** (*well established*). This is why land and soil policy gained increasing international recognition with respect to climate change negotiations of the 23rd Conference of the Parties to the United Nations Framework Convention on Climate Change (UNFCCC COP 23) held in Paris in 2015 when the '4 per 1000 Initiative' was launched by the French Government. The initiative promotes enhancement of soil quality, carbon sequestration and soil conservation through improved agricultural practices that mitigate climate change. {15.3.1, 15.4}

**High-consumption lifestyles, especially in developed economies, aggravated by food waste, and rapid population growth rates have negative consequences for land and its resources** (*established but incomplete*). The increased demand for food and biofuels will trigger agricultural intensification such that biomass production is expected to double by 2050. Policies need to steer sustainable intensification through conservation agriculture practices to mitigate negative effects on soil health and on the environment. {15.2.4}

**Land-use planning, sustainable use of land resources and sustainable land management are the answers to balance production with environmental protection** (*well established*). Sustainable intensification practices attempt to integrate increasing crop yields with maintaining soil fertility and improving water-use efficiency. Annually, US\$75.6 trillion can be gained from implementing global policies that enable sustainable land management. Among many other sustainable land management practices, conservation agriculture that includes also zero tillage provides a good example of technologies that maintain land quality, enhance soil carbon sequestration, mitigate climate change, protect biodiversity and sustain productivity. Policies, economic analysis, science and farming incentives, however, are all necessary to support implementation of these technologies, especially for small landowners, in particular those in the developing countries. {15.2.4}

**Land management, restoration and policies need to be tailored according to local conditions** (*well established*).

Experience has shown that 'one-size-fits-all' is not an option to promote sustainable land management worldwide. Success of policy implementation depends on a number of factors that consider an integrated landscape approach well-matched to socioeconomic and natural characteristics supported by good levels of governance and stakeholder engagement. {15.2.4, 15.2.5}

**Implementing the right actions to combat land degradation and support sustainable land management policies has a direct effect on the livelihoods of millions of people across the planet** (*well established*). This imperative will become more difficult and costlier if no action is taken urgently. Unfortunately, there is still a disconnect between consumers and the ecosystems that provide the food and other commodities they depend upon. {15.5}

**Land is a finite resource that is under human pressure, especially from urban sprawl** (*established but incomplete*).

Chaotic urban expansion has been observed worldwide mostly on fertile and productive lands and, by 2050, about 80 per cent of the productive soils are at risk of being lost as each year about 20 million ha of agricultural land is converted into urban and industrial developments. The situation along the coastal areas is worst. It is therefore imperative that land-use policies should define a proper allocation of land resources between competing interests. Cities play a major role in land-use changes, so municipal and city planners need to coordinate their actions with a large number of stakeholders, including civil society and establishing public-private partnerships, to ensure sustainable spatial planning, policy coherence, implementation and conflict resolution for both urban settlements and responsible food systems. {4.2.5, 15.3.3}

## 15.1 Introduction

As noted in chapter 8, land plays a crucial role within the 'Healthy Planet, Healthy People' theme and underpins global efforts towards sustainable development. Consequently, sustainable land management (SLM) is not only essential to promoting and maintaining the great diversity of nature's contribution to people but also in tackling poverty and hunger.

At the international level, the Sustainable Development Goals (SDGs) emphasize the need for SLM among stakeholders for the protection of natural ecosystems that are on the verge of collapse, including increased climate-induced natural disasters. SDG 15 is directly related to the analysis in Chapter 8. Furthermore, SDG target 15.3 focuses on land by demanding action against land degradation and efforts to achieve a land degradation-neutral world. Although land management is explicitly targeted in SDG 15.3, it is paramount for food security (SDG 2), climate action (SDG 13) and also has many interconnections with SDGs 1, 3, 6, 7, 11 and 12 (**Figure 15.1**).

The driving forces and pressures (see Chapter 2) on land and its resources emanating from population growth, urbanization, economic development, technology and innovation, and climate change have elicited responses at global, regional and

### Box 15.1: The Concepts of Land and Soil

The concepts land and soil are not synonyms. Land represents the terrestrial solid part of the earth that is not permanently under water and offers an endless set of services and functions from biomass production to urban living habitats. It comprises soil, vegetation, other biota, and the ecological and hydrological processes operating on it. Soil is the unconsolidated material on the land surface that has been formed by mineral particles, organic matter, water, air and living organisms simultaneously interacting over time. Ecological processes in the soil ensure biomass production, nutrient cycling, carbon sequestration, water filtration and buffering, cooling and hosting biodiversity.

**Figure 15.1: Linkage between the land-related SDG target 15.3 and other SDGs**

national levels. At the global level, several responses directly or indirectly related to sustainable land and soil management have been initiated as shown in **Table 15.1**.

This chapter provides a comprehensive overview of the current Land and Soil policy framework and the related shortcomings, especially in terms of policy cohesion and implementation, as well as overall effectiveness. The subsequent sections present case studies of different sets of legal and policy instruments, economic tools and incentives, as well as policies and programmes implemented across different countries. The case studies were selected based on the criteria of regional balance, different spatial scales, type of policies and/or governance arrangements, plus their relevance to state and trends of land resources as detailed in Chapter 8 of this report.

## 15.2 Key policies and governance approaches

An overview of key policies and respective case studies is provided in **Table 15.2**. The cases reflect the variety of driving forces, economic sectors and processes affecting land degradation, and are used as illustrative examples of policy instruments covering a diverse range of spatial scales and time frames of implementation. Despite addressing important drivers and respective policy approaches, the cases here do not

address two further key aspects of land degradation that were pointed out in Chapter 8, namely insecure land tenure systems and land grabbing issues on the one side (Section 8.5.3), and teleconnections and spillover effects of consumption of land-based products (food, bioenergy) in one country on land resources depletion in other countries (Section 8.4.1). Both these issues severely affect the social dimension of land degradation impacts (IPBES 2018a).

#### 15.2.1 Funding programmes and standard setting for best management practices

Sustainable land management is strongly influenced by policy frameworks that differ between countries and regions. A main driver is land-use change that has distinct economic and environmental consequences. Economic gains often are responsible for environmental degradation and, in many cases, not all stakeholders benefit from such gains (Castella *et al.* 2013). The case study below looks at these dynamics.

##### **Case study: Strengthening foreign direct investment management and social and environmental safeguards in Lao People's Democratic Republic (Lao PDR).**

Foreign investments in Lao People's Democratic Republic have a direct impact on the economic growth of the country and account for more than 50 per cent of gross domestic product (GDP), but they also raise serious environmental issues as the country has been experiencing significant forest depletion since the 1980s. Forests covered nearly 50 per cent of the country in 1982 (Phompila *et al.* 2017), but had declined to 41.5 per cent by 2013.

There are a number of factors that have influenced forest decline (Food and Agriculture Organization of the United Nations [FAO] 2010). They derive mostly from economic activities, such as forest land conversion for agriculture, mostly cash crops, and urban sprawl associated with infrastructure expansion and hydropower production. Other driving forces accelerating deforestation include uncontrolled hunting and logging as well as cleared forest areas converted to livestock grazing (United Nations Development Programme [UNDP] 2014). Economic activities emanating from forest land conversion for agriculture have triggered an increase in the number of land deals in Lao PDR 50-fold from 2000 to 2009 (Schonweger *et al.* 2012). The value of approved foreign and domestic investment projects exceeded US\$29 billion by March 2018. All except for US\$3.9

billion of this total was generated through foreign investment (US\$8.5 billion) or joint ventures (US\$16.6 billion) (UNDP-United Nations Environment Programme (UNEP) Poverty-Environment Initiative, UNDP and UNEP 2018).

The second largest type of land concession is related to agricultural investments. Between 1990 and 2007, the area of plantations, especially rubber plantations, increased dramatically from 1,000 ha to over 200,000 ha (Phimmavong *et al.* 2009). As of 2012, these covered more than 330,000 ha. An early study found that 85 per cent of all investment in agricultural concessions came from foreign investors, the five most important being from China (about 50 per cent), Thailand, Viet Nam, Republic of Korea and India (Wellmann 2012). Estimates of the area given to land concessions alone vary between 330,000 ha and 3.5 million ha, but the government has reported that 1.1 million ha was a conservative estimate. This is equivalent to 5 per cent of national territory or 18 per cent more than the total arable land in Lao People's Democratic Republic (Global Witness 2013). Thirteen per cent of all villages in Lao PDR have at least one concession within their village boundaries (Wellmann 2012).

Vast parts of communal lands that lack tenure titles are the target of big foreign companies, which have expanded their land acquisitions in Lao People's Democratic Republic. Unfortunately, this process is accompanied with a new poverty type that affects local people who become dependent on new investors for all of their basic livelihood needs (Messerli *et al.* 2015). In one case, 25 villages were displaced due to a land concession to a Vietnamese rubber company and local communities were prevented from accessing the natural resources upon which they based their livelihood (UNDP and UNEP 2013).

In response to the challenges presented by sustainable development of the environment and natural resources, and at the invitation of the Government of Lao People's Democratic Republic, the joint United Nations Development Programme-United Nations Environment Programme (UNDP-UNEP) Poverty-Environment Initiative supported the government from 2009 to 2015 in developing tools to guide promotion, screening, approval, monitoring and compliance enforcement of investments, and helped build the capacity of institutions to engage with impacted communities and respond to unintended social and environmental impacts of investments in key natural resource sectors. **Table 15.3** gives a summary of the assessment criteria.

Table 15.3: Summary of the assessment criteria for foreign investments

| Criterion                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | References                                                                   |
|-----------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------|
| <b>Success or failure</b>         | Success criteria include: benefits derived from the Poverty-Environment Initiative: a first green and pro-poor, quality investment management system; the assessment of development options; greater understanding of positive and negative investment implications; awareness of investors' degree of compliance; improved accountability; and the introduction of the 'green-growth' concept. Although training events and capacity-building took place, several relevant actors, at national and local levels, are not empowered to understand and enforce an equitable investment management system. Notwithstanding capacity-building events, uneven governmental capacity remains a challenge, but officials are showing commitment and appreciation. The lack of clear assignment of responsibilities in investment management remains unaddressed.                                                                                                                                                             | Tavera (2015)                                                                |
| <b>Independence of evaluation</b> | The assessment of this Lao PDR experience is part of the Initiative's independent midterm evaluation. Phase I (2009-2012) and Phase II (2012-2015) have been evaluated by an independent consultant at the request of the United Nations Development Programme Country Office.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                                                                              |
| <b>Key actors</b>                 | The Poverty-Environment Initiative country team worked closely with the Lao PDR National Assembly, the Ministry of Planning and Investment, the Department of Environment and Social Impact Assessment, the Ministry of Natural Resources and Environment, the Investment Promotion Department and the National Economic Research Institute.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                                                                              |
| <b>Baseline</b>                   | Before the commencement of the programme in 2011, annual average GDP growth was 7.9 per cent in the preceding decade (Lao People's Democratic Republic, Ministry of Planning and Investment 2011), while the poverty level was 27 per cent in 2007 (World Bank 2010). In 2010, Lao PDR had a GDP per capita of US\$1,101.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                                                                              |
| <b>Time frame</b>                 | Phase I took place from 2009 to 2012, Phase II from 2012 to 2015. Phase III (2016-2018) is not included in this case study.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                                                                              |
| <b>Constraining factors</b>       | There is an urgent need to build poverty-environment awareness and capacity within the National Assembly to make its normative work effective. Although technical staff of the National Assembly received training on compliance, the capacity-building efforts of the Initiative are limited and need to be sustained and expanded. Capacity needs to be strengthened also at the ministerial and, especially, local levels – fundamental for implementation and often hard to reach. Inter-ministerial and vertical coordination (especially with provinces) should be improved to achieve integrated development and equitable investment management.                                                                                                                                                                                                                                                                                                                                                               |                                                                              |
| <b>Enabling factors</b>           | Governmental commitment and involvement are major enabling factors, in particular with respect to the National Assembly, but also with the Investment Promotion Department and development-related ministries (the participation of the Ministry of Planning and Investment was fundamental). Shared and increased poverty-environment awareness by reference managers and staff resulted from the Initiative's efforts and allowed for the prioritization of equitable investment management. Improved assessments and investment data management had started to inform decision-making and create understanding of whether investments were economically beneficial for communities.                                                                                                                                                                                                                                                                                                                                 |                                                                              |
| <b>Cost-effectiveness</b>         | Foreign direct investments are forecast to lead the country's development and comprise a significant share of its GDP. Their proper management is an important contribution to sustainable and equitable economic growth.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                                                                              |
| <b>Equity</b>                     | Management of foreign direct investments directly addresses equity with regard to impacted communities. Unregulated investing led to cases of village displacement, land grabbing or segregation of resources vital to the livelihood of inhabitants, without necessarily contributing to the country's development (creating local jobs or providing significant revenues to the national government). With the support of the Poverty-Environment Initiative, Lao PDR was able to provide a legal framework and safety net to bind investments to more equitable conditions. This work also contributed to creating awareness among decision makers about equitable sustainable development and to orient the National Assembly and future national development strategies towards this aim. This was already clear during Phase I, which saw the 7th Five-Year National Socio-Economic Development Plan (2011-2015) integrate poverty-environment issues and highlight the objectives of quality growth and equity. | Lao People's Democratic Republic, Ministry of Planning and Investment (2011) |
| <b>Co-benefits</b>                | Tackling the equity dimension in investment management also has external positive implications on the environmental side. It promotes more inclusive and sustainable land management and prevents the depletion of natural resources and biodiversity loss. These practices lead to economic benefits being more fairly distributed among local communities. These points highlight how all three dimensions of sustainable development (economic, social and environmental) are addressed. The Lao PDR case also provides a relevant example of foreign direct investment management for sustainable development that can be shared through South-South learning. The Lao PDR experience has further informed the work of the Poverty-Environment Initiative country projects in Myanmar, Mongolia and Philippines, in particular on investments in extractive industries.                                                                                                                                            | Choi and Gankhuyag (2016)                                                    |

| Criterion                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | References |
|------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------|
| <b>Transboundary issues</b>  | A more binding investment regulation system might lead investors to flee to other countries with a laxer framework and where standards for compliance are lower. To avoid this, investment management performance should be enhanced, and working with the whole region could harmonize standards. The Lao PDR experience could serve countries beyond Asia and the Pacific, as it is relevant to global efforts to promote inclusive and greener economic growth.                                                                                                                                                                                                                                                             |            |
| <b>Possible improvements</b> | <ul style="list-style-type: none"> <li>❖ Realize a financial sustainability strategy for investment management, owned by the Investment Promotion Department and the Ministry of Finance, to make investment management sustainable.</li> <li>❖ Enhance data sharing among relevant ministries to promote coordination for management of investments.</li> <li>❖ Strengthen enforcement for compliance.</li> <li>❖ Intensify training and ownership of tools for all actors involved, especially at the local level.</li> <li>❖ Improve management of foreign direct investments in the whole region to avoid investors fleeing to contexts with lower standards.</li> <li>❖ Strengthen communities' participation.</li> </ul> |            |

An independent evaluation of the joint UNDP-UNEP Poverty-Environment Initiative programme conducted in 2016 rated its performance as "highly satisfactory". The effectiveness of this equitable and comprehensive legal framework is, however, subject to implementation and enforcement that go beyond the programme. The main obstacles to enforcement are lack of institutional capacity, tools and funds for investment monitoring. There are efforts to fill the information gap including improving database management for monitoring compliance. Yet, poor institutional coordination still prevents this data from generating consistent action on compliance and enforcement. There is also limited opportunity for community inputs into the national decision-making process (Tavera 2015; Tavera, Alderman and Nordin 2016). On the other hand, the conditions for equitable and sustainable growth have been laid. The policy effort was successful in providing comprehensive and fair tools and processes to enable quality investments and safeguard communities. There is now a legal framework to empower these actors to take part in development processes, and the country is moving one step closer to ensuring that investment is judged by the quality of its social and environmental benefits – and not just its benefits in economic terms. Community engagement was also enabled (UNDP 2016). These efforts in the investment sector also contributed to increasing decision makers' awareness and political prioritization of sustainable development.

### 15.2.2 Planning and compensation for halting desertification

The success of any strategy for combating desertification depends on the implementation of sustainable land and water management practices adapted to the specific local geo-biophysical and socioeconomic situation. Well-managed soils slow down the process of land degradation, regulate the water cycle, safeguard biodiversity, conserve landscape multifunctionality and improve the provision of ecosystem services (United Nations Convention to Combat Desertification [UNCCD] 2017a; Zdruli and Zucca 2018).

The general policy approach for combating desertification in terms of the DPSIR framework (section 1.6) needs to tackle the pressure derived from land cover losses, which in many cases are driven by economic incentives to increase agricultural production. Effective policy approaches generally

combine command-and-control policies (in extreme cases, forcing farmers to stop farming) and offering incentives, such as subsidized tree planting. The Land Degradation Neutrality approach, included in SDG 15.3 and endorsed by the UNCCD, and the Economics of Land Degradation Initiative have become the mainstream strategic instruments to reduce net losses of land resources and ensure their sustainable management (Akhtar-Schuster *et al.* 2017; UNCCD 2017a); they also address climate change (Sanz *et al.* 2017). A set of management practices – including sustainable soil/land and water management, afforestation and reforestation, agroecology, pasture improvement and controlled grazing, watershed management, water harvesting and sustainable agricultural practices – have been implemented in support of this goal (Rojo *et al.* 2012; Schwilch, Liniger and Hurni 2014; Teshome *et al.* 2015; Marques *et al.* 2016).

Land restoration projects are usually funded with public money and follow top-down approaches (Marques *et al.* 2016). The top-down approach is traditionally applied by national governments, and as such these instruments are often called 'command-and-control' or regulatory instruments (King and Mori 2007; Weber, Driessen and Runhaar 2014). The government defines the rules and norms, and has the right to apply sanctions in those cases where rules are not implemented. Examples of regulatory instruments include standards, bans, permits, zoning and use restrictions (Lambin *et al.* 2014; Weber Driessen and Runhaar 2014). The 'command-and-control' approach is often implemented especially in the developing countries, as can be seen in the following case study.

#### Case study: The Great Green Wall to effectively decrease dust storm intensity in China

The Chinese Great Green Wall (GGW) is one of the most ambitious projects to combat desertification and control dust storms, similar to the Sahara Great Green Wall stretching from Dakar to Djibouti. The project was originally named the Three North Shelterbelt Forest programme, as launched in 1978; it still retains that same name but is also called the GGW. It is expected to continue until 2050. The programme name has become a common term in China, as the largest afforestation project in the country (Huang *et al.* 2016). It was designed to cover a total area of 4.1 million km<sup>2</sup> (or 42.7 per cent of the total land area of the country **Figure 15.2** (Wang *et al.* 2010).

| <b>Success or failure</b>         | Chinese researchers and government officials have reported that afforestation has successfully combated desertification, accelerated soil carbon sequestration and decreased soil erosion. By 2012, the programme had reportedly increased the tree cover from 5 per cent to 12.4 per cent in the programme area, with the cumulative tree planting area reaching 26.47 million ha. The policy showed success in that it reversed the trend of land degradation such that in many places soil carbon sinks are starting to increase. Vegetation cover increased in the GGW region compared to non-GGW regions, which led to a reduction of the dust storm intensity in northern China. During the project, desert expansion has been reduced to about 10 km <sup>2</sup> per year. In addition, about 1,060 km <sup>2</sup> of desert per year is transformed in a good condition.<br>Critics of the programme, however, claim that it may have failed to meet its goals to date. One reason is that the observed decrease of dust storm intensity may simply be a consequence of climatic variability. Second, the programme was implemented only on a small portion of the affected areas and even not those that are known as core areas for dust storm sources. Third, not all of the planted trees and shrubs survived beyond the lifetime of the programme because of mismanagement and/or lack of water. A further point of critique was related to the overuse of groundwater by planting varieties that were not well suited to the arid areas. | Piao <i>et al.</i> (2007); Wang <i>et al.</i> (2010); State Forestry Administration (2011); Deng, Liu and Shangguan (2014); Sternberg, Rueff and Middleton (2015); Tan and Li (2015); Feng <i>et al.</i> (2016); Jiang (2016); Ahrends <i>et al.</i> (2017) |
| <b>Independence of evaluation</b> | There has been no independent evaluation, other than those conducted by Chinese researchers reported above.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                                                                                                                                                                                                                                                             |
| <b>Key Actors</b>                 | The key actor and investor is the Government of China, with 18 ministries and agencies of the central government and local authorities involved in various aspects of policy formulation concerning desertification control. The State Forestry Administration (SFA) is responsible for coordinating activities among these ministries. The local residents and communities have been involved in afforestation, grassland establishment and related activities. The programme additionally looks for the dynamic cooperation of non-governmental domestic and international entities, including the broad involvement of the private sector.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | Lu and Wang (2003); State Forestry Administration (2011); Yin and Yin (2010)                                                                                                                                                                                |
| <b>Baseline</b>                   | Since 1980, dust storm events were classified into ten grades (0-9) according to a visibility range that was being monitored at meteorological stations. The so-called Dust Storm Index (DSI) is equal to the mid value of the visibility for each grade. Despite considerable annual variation, a strong decrease of DSI has been observed since 1985. Also, the number of sandstorm days decreased and reached a low level in 1996. However, because of the complex interactions with vegetation, it was not possible to draw a clear, one-to-one cause-effect relationship between the implementation of the policy and the decrease of dust storm events.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | Tan and Li (2015); Xiaoming <i>et al.</i> (2016)                                                                                                                                                                                                            |

| <b>Constraining factors</b>  | The excessive population growth of human and livestock is a challenge to the limited ecological carrying capacity in desertification-prone areas around the world (Pan <i>et al.</i> 2013) including in China. In the past decade alone, China invested more than US\$100 billion into six key forestry programmes. However, returns for the large-scale tree planting investment in marginal areas may be low or take a long time to materialize. Another shortcoming is related to lack of interest from farmers after the trees have been planted, and lack of knowledge in forest management. Less supervision from local governmental offices and the size of subsidy levels were issues that limited the policy impact effect. Overall, the lower subsidies did not offer a strong motivation for farmers to participate in the programme despite the large amounts of money invested in ecosystem payment schemes to meet Chinese Government ambitions.                                                                                                                                                                                                                                                                                                                                                                                                                                | Ahrends <i>et al.</i> (2017) ;<br>Xu, Song and Song (2017)                                                                   |
| <b>Enabling factors</b>      | A large number of institutional and administrative capacities have underpinned success to date. Since 1997, the SFA has established several institutions dealing with desertification, including the National Bureau to Combat Desertification, the National Desertification Monitoring Centre, a National Training Centre for Combating Desertification, and a National Research and Development Centre for Combating Desertification – all to conduct research and implement policy programmes on desertification issues. Moreover, in June 2009, the Institute of Desertification was established by the Chinese Forest Academy, which is also under the SFA. The government strongly supports desertification mitigation programmes by allocating significant funding (US\$4 billion total during the initial 28 years). Several compensatory measures to increase vegetation have been implemented, including cash incentives to farmers willing to plant trees and shrubs.                                                                                                                                                                                                                                                                                                                                                                                                              | Jiang (2016)                                                                                                                 |
| <b>Cost effectiveness</b>    | “For the period from 2002 to 2006 the Three North Shelterbelt Forest Project has used 4,147 million yuan (US\$545.6 million) of investment, created 2,840 million yuan (US\$373.7 million) of ecological benefits, and 8,060 million yuan (US\$1,060.5 million) of economic benefits.” Direct costs of desertification are estimated at 64.2 billion yuan (Chinese Yuan Renminbi - CNY) annually (US\$7.7 billion), while indirect costs of desertification are estimated at 288.9 billion yuan annually. Finally, the analysis shows that the costs of the rehabilitation of the lands degraded due to land use cover change are significantly lower than the costs of inaction, with returns of up to 4.7 times for every yuan invested over a 30-year period.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | Deng and Li (2016);<br>Jiang (2016)                                                                                          |
| <b>Equity</b>                | Desertification control has mostly depended on the administration, specialists and other social elites for decision-making, while the local people are often inactively participating in the decision-making process. For instance, the local communities did not have the right to decide on control measures of the ‘Sand Control Law’.<br>In order to enhance land restoration of degraded areas, the government allocated land-use rights to local people for up to 70 years. This type of policy improved the land tenure issues and increased interest from local people. Government resettled farmers and herders on degraded lands and provided subsidies and compensations for those who participated in restoration activities. However, there is no systematic compensation method or proper regulations in land desertification control to support local people.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | (Jiang 2016)                                                                                                                 |
| <b>Co-benefits</b>           | Polycyclic aromatic hydrocarbons, also known as polyaromatic hydrocarbons, are organic compounds containing only carbon and hydrogen and can be dangerous to human health with cancer being the primary health risk from exposure to them. The implementation of the Three North Shelterbelt Forest Project resulted in atmospheric removal and long-term reduction trends of two polycyclic aromatic hydrocarbon species, phenanthrene and benzo[a]pyrene.<br>A series of studies on the health effects of dust storms in north-western China show that dust events were significantly associated with respiratory and cardiovascular hospitalization (after adjusted the effect of SO <sub>2</sub> and/or NO <sub>x</sub> ). Events like this are also recorded in India, where in May 2018 it turned to be deadly. Based on published research (e.g. Tan and Li 2015; Wang <i>et al.</i> 2012), the frequency and severity of dust storm events have diminished over time thanks to the interventions of the GGW project that, according to the statistical data from National Meteorological Information Center, China (e.g. Tan and Li 2015), has positively affected the health status of the people living in the region and beyond.<br>The other social-economic benefit of the project has been the development of tourism and increasing employment opportunities for local people. | Aunan and Pan (2004);<br>Li and Huntsinger (2011);<br>Huang <i>et al.</i> (2016)                                             |
| <b>Transboundary issues</b>  | From the global assessment report on sand and dust storms, it is clear that sand and dust storms from the desert areas of China and Mongolia affect the air and ocean quality as far as Korea, Japan, Pacific Islands and North America (e.g. <a href="https://youtu.be/jGPuCeEILeM">https://youtu.be/jGPuCeEILeM</a> ). Furthermore, there is a Regional Master Plan for the Prevention and Control of Dust and Sandstorms in Northeast Asia, a project involving the governments of China, Japan, Mongolia and Republic of Korea. The goal is to mitigate health effects deriving from dust storms from this region outside north-west China (e.g. in Japan, Korea), emphasizing the long-range transport and the transboundary nature of these events and the need for regional cooperation. Desert dust also plays an integral role in the Earth system affecting air chemistry and climate processes, soil characteristics and water quality, nutrient dynamics and biogeochemical cycling in both oceanic and terrestrial environments.                                                                                                                                                                                                                                                                                                                                                 | Goudie and Middleton (2006); Abiodun <i>et al.</i> (2012);<br>UNEP, World Meteorological Organization [WMO] and UNCCD (2016) |
| <b>Possible improvements</b> | Research data from similar ecological areas in the Loess Plateau in China showed that there is competition for water resources between the afforested vegetation and the human water needs. Hence government decisions and policies to combat desertification must be compliant with ecological and people's socioeconomic demands without disturbing the water balance in these areas. This could be achieved by protecting local vegetation in desertification-prone lands and planting suitable vegetation according to local conditions or in specific cases leaving the land to recover without human disturbance.<br>While considering multiple ecosystem services and their potential consequences rather than focusing only on a few services and ignoring other influences, GGW could be a role model for other regions with similar natural conditions. However, the reduction of production of agricultural goods coming along with GGW implementation triggers an increase in agricultural production elsewhere, either within the country or abroad. Respective spillover effects on potential land degradation associated with intensified agricultural production have not been analysed adequately to date.                                                                                                                                                                   | Xiaoming <i>et al.</i> (2016)<br><br>Ahrends <i>et al.</i> (2017)                                                            |

GGW is not the only project in China dealing with afforestation. For instance, the Grain for Green programme is being implemented over millions of hectares of crop- and grassland that are degraded or were at high risk of degradation had the farmland practices in use continued (Shuai *et al.* 2015; Xiaoming *et al.* 2016). Another example is the Beijing-Tianjin Sand Source Control programme that looks at ecological restoration and implementation of different types of management practices ranging from controlled grazing and associated restrictions to cropland conversion to forest or grassland not being used for grazing (Middleton and Kang 2017). The experience gained from the Three North Shelterbelt Forest programme was crucial for drafting the National Action Plan (NAP) to combat desertification in China. The first NAP was prepared in 1996, coinciding with the creation of the UNCCD, and was revised in 2003. It was the first NAP in the world to have a monitoring follow-up system to measure the trends of desertification.

The public-private partnership mode, especially with the Elion Resources Group Foundation, is proving very successful. In 2015, the UNCCD awarded the Elion Foundation with the prestigious Land for Life Award for improving the livelihoods of 100,000 farmers and herders in the Kubuqi Desert in Inner Mongolia and for recovering 11,000 km<sup>2</sup> of degraded land into productive areas and promoting the production of green energy.

The GGW's trees provide a barrier against desert winds and help hold moisture in the air and soil, allowing plants to grow. In spite of the very high costs of its implementation, this programme is cost-effective especially for improving human health, biodiversity and livelihoods. Therefore, the Chinese Government plans to expand the reforestation programmes.

### 15.2.3 Setting threshold values for policy and overall governance on remediation of contaminated land

Pollution is the world's leading environmental cause of disease and premature death (Landrigan *et al.* 2018), and increasing land contamination globally is affecting the sustainability of the land resources and their ability to support life systems (Plant *et al.* 2001; Ballabio *et al.* 2018; Rodríguez-Eugenio, McLaughlin and Pennock 2018). Approximately 342,000 contaminated sites were identified in Western Europe (European Environment Agency [EEA] 2014), while in the United States the Office of Land and Emergency Management (OLEM) oversees 540,000 contaminated sites, impacting 9.3 million ha (Pierzynski and Brajendra eds. 2017) and the Environmental Protection Agency manages approximately 1,400 highly contaminated sites (United States Environmental Protection Agency 2014). Contaminated land containing substances that are potentially hazardous to public health and the environment is found in many places around the world (Tóth *et al.* 2016). Land contamination results from mining, industrial activities, military action, farming, chemical and oil spills and waste disposal (Rodríguez-Eugenio, McLaughlin and Pennock 2018). Secondary soil salinization through excess or unsuitable irrigation is a further, yet unexplored process that threatens human health (Hamidov, Helmin and Balla 2016).

The Stockholm Convention on Persistent Organic Pollutants (POPs), which entered into force in 2004, is one of the Multilateral Environmental Agreements dealing with global policies and treaties to protect human health and the

environment. It asks its Parties to adopt measures to eliminate POP releases (UNDP 2009). Many countries have already ratified this convention and are implementing various land remediation policies in compliance with the global treaty. Other conventions dealing with hazardous waste movements between countries and imports of hazardous chemicals include the Basel and Rotterdam Conventions, which have also been ratified by a number of Parties, but have significantly different obligations (Secretariat of the Basel, Rotterdam and Stockholm Conventions 2018).

Generally, land remediation policies adopt mandatory command-and-control approaches, mainly utilizing the 'polluter pays' principle (Rodrigues *et al.* 2009). Nevertheless, in most cases public financial resources are required to clean already polluted areas for the benefit to the common good. Within the DPSIR framework (Section 1.6), this policy approach targets the state of the environment, intending to reduce the quantity of pollutants in the soil. Several national governments have taken concrete steps, including the establishment of relevant policies and institutional frameworks, for the remediation of contaminated lands (Rodrigues *et al.* 2009; EEA 2014). A good example comes from China, which in 2018 approved a new law on soil pollution prevention due to enter into force in January 2019 (Xinhua 2018). The case study below examines the remedial treatment of Agent Orange-contaminated land in Viet Nam as adequate data are available to evaluate the policy outcomes, in contrast to many other sites where such data are missing.

#### Case study: Viet Nam remedial treatment of Agent Orange-contaminated land

Viet Nam has some of the worst contaminated lands in the world (Lupi and Hoa 2015), which occurred as a result of 2,3,7,8-Tetrachlorodibenzodioxin (TCDD or Agent Orange) contamination as a result of the Viet Nam (or Second Indochina) War (1955-1975). During this war (1961-1972), the United States army used herbicides (Agent Orange) against Vietnamese military installations and this eventually resulted in land contamination, and destruction of vegetation and crops. Decades after the conflict, the Government of Viet Nam initiated the dioxin decontamination programme (Environmental remediation of dioxin contaminated hotspots in Viet Nam) as part of its National Implementation Plan (NIP), developed in line with the regulations of the Stockholm Convention. The programme aims to decontaminate the most heavily polluted areas, to plant trees on 300,000 ha of contaminated land, to help all dioxin victims, offer allowances and health insurance for people with disabilities and enhance research into the effects of toxic chemicals. **Table 15.5** provides a summary of the assessment criteria.

Viet Nam has implemented the land remediation policy backed by a complete framework of laws and regulations with supports from the United States of America, UNDP and some philanthropic foundations. Overall, the policy is positive and effective in meeting its initial objectives, but this is a process that should be based on a long-term strategic planning and monitoring programme. Note that this is a particular case, so policies that should address contaminated lands must reflect local conditions, national regulatory frameworks accomplished by internationally agreed conventions. Budgetary constraints and limitations should not be the justification for non-action when public health and the well-being of entire communities and ecosystems are at stake.

**Table 15.5: Summary of the assessment criteria for land decontamination in Viet Nam**

| Criterion                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | References                                                                                           |
|-----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------|
| <b>Success or failure</b>         | There are very few cases where dioxin-polluted soil has been effectively decontaminated and it appeared that the only viable solution in most countries has been land filling. The United States Environmental Protection Agency (EPA) states that, "remediation technologies for the clean-up of dioxin-contaminated soils and sediments are still being developed, and many of the accepted techniques rely on thermal destruction." The Viet Nam case shows some sort of success, as the spreading of TCDD in the environment was minimized thanks to the correct implementation of the NIP plan.                                                                                                                                                                                                          | United Nations Industrial Development Organization [UNIDO] (2012); Lupi and Hoa (2015)               |
| <b>Independence of evaluation</b> | Most of the evaluation work has been carried out by independent assessments commissioned by UNDP, USAID and UNIDO.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | United States Agency for International Development [USAID] (2010); UNIDO (2012); Lupi and Hoa (2015) |
| <b>Key actors</b>                 | The key actors in the implementation of the policy include the Ministries of Defence, Environment and Natural Resources, Office 33 Committee, and the Department of Health. Stakeholders that provided the technical and financial assistance were also considered as key actors and included USAID, Czech experts, Bill & Melinda Gates Foundation and the Ford Foundation.                                                                                                                                                                                                                                                                                                                                                                                                                                  | Lupi and Hoa (2015)                                                                                  |
| <b>Baseline</b>                   | About 45,000 m <sup>3</sup> of Agent Orange were sprayed by the United States military in about 10 per cent of the then South Viet Nam territory. About 4.8 million Vietnamese people were impacted by the contamination. Over 3 million Vietnamese were exposed to health challenges as a result of the contamination. In response to this, the United States Congress made a financial commitment of US\$59.5 million for decontamination of the affected lands and related health-care activities in Viet Nam between 2007 and 2012. The estimated volume of dioxin in hotspots released to the environment was 1,736 g I-TEQ, while the volumes of soil remediated at Bien Hoa, Da Nang and Phu Cat were at least 100,000 m <sup>3</sup> , 70,000 m <sup>3</sup> and 2,500 m <sup>3</sup> , respectively. | Lupi and Hoa (2015)                                                                                  |
| <b>Time frame</b>                 | The process of remedial treatment of the Agent Orange-contaminated land commenced in 1999 with the issuing of Decision 33 which established the National Steering Committee 33 charged with the responsibility of coordination of all Agent Orange-related matters. This was followed by the ratification of the Stockholm Convention, which targeted the phasing out POPs. The time frame for the evaluation of success or failure of the Agent Orange remedial activities was five years.                                                                                                                                                                                                                                                                                                                   |                                                                                                      |
| <b>Constraining factors</b>       | The constraining factors include poor planning and absence of a robust regulatory framework regarding dioxin contamination, inadequate data on dioxin-contaminated lands and weak technological capacities. Other factors are the weak capacities of government ministries and departments for coordination of remediation activities and limited funds available.                                                                                                                                                                                                                                                                                                                                                                                                                                            | UNDP (2009)                                                                                          |
| <b>Enabling factors</b>           | There are several enabling factors, including the political will on the part of the government, which promoted the establishment of the relevant policy and institutional framework for the implementation and coordination of remedial activities. The support of the United States Government and the philanthropic support from the Bill & Melinda Gates Foundation and the Ford Foundation were critical enabling factors that facilitated the remedial treatment of contaminated lands.                                                                                                                                                                                                                                                                                                                  |                                                                                                      |
| <b>Cost-effectiveness</b>         | There is little information on the cost-effectiveness of the land remediation programmes, both in Viet Nam and elsewhere. However, an evaluation of cost-effectiveness of a land remediation programme in the Dominican Republic in a lead-contaminated site indicates that remediation activities reduced health burden associated with land contamination to an acceptable cost and thresholds in line with World Health Organization (WHO) standards.                                                                                                                                                                                                                                                                                                                                                      | Ericson <i>et al.</i> (2018)                                                                         |
| <b>Equity</b>                     | The involvement of the local communities both in designing project-supported activities and their implementation promoted local participation and ownership, which helped to promote the equity dimension of the policy. Another policy equity dimension is the promotion of access to land that has become usable after the implementation of the remediation programmes.                                                                                                                                                                                                                                                                                                                                                                                                                                    | Lupi and Hoa (2015)                                                                                  |
| <b>Co-benefits</b>                | People and communities affected by dioxin contamination may benefit from employment opportunities during remediation activities. Also, business activities around the airport have benefited from remediation as more viable lands were made available. The project generated considerable health benefits for the country. Without action, the dioxin contamination would have spread, posing severe risk to human health and the environment. Apart from neutralizing the dioxin contamination, a considerable part of the project also focused on health education and risk reduction activities among the communities in the vicinity of the contaminated hotspots. This promoted positive health among the people.                                                                                       | University of the West of England, Science Communication Unit (2013)                                 |
| <b>Transboundary issues</b>       | There are no potential transboundary issues in the implementation of the policy, despite the fact that neighbouring countries were also affected during the Viet Nam war by the same form of contamination.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                                                                                                      |
| <b>Possible improvements</b>      | Viet Nam has demonstrated a strong commitment to land remediation policy, but it is not clear what quantity of the contaminated lands have been remediated. This is an important variable needed to accurately assess the policy effectiveness of the decontamination programme.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                                                                                                      |

#### 15.2.4 Provision of consultancy and networking for agricultural innovation

One generic policy type is the promotion of innovation by land users and farmers alike. It uses instruments such as incentives and provision of education and extension services. Some of the innovation technologies that have expanded over the last two decades include no-tillage (NT) and conservation agriculture (CA). In fact, the two practices are complementary to each other and accomplish similar goals. While NT is not a primary practice in CA, CA is based on two other principles – the introduction of cover crops and crop rotations (Kassam and Friedrich 2011). NT and CA were initially developed to combat soil erosion; however, they can also optimize crop production, promote soil health by keeping soil organic matter and nutrients in place, and by improving water and air quality. NT and CA are both seen as community-driven development processes of acceptance of new principles of agriculture. Yet their global share is limited. NT is primarily practised in North America (32 per cent of the global area under NT) and South America (45 per cent). CA, on the other hand, covers about 11 per cent of the total cropland globally and like NT is most widely located in North and South America that together have 76.6 per cent of the total CA area. Europe is lagging behind with only about 7 million ha, largely found in Russian Federation, France, Spain and Italy (FAO 2016).

NT and CA farming are seen as very promising in terms of soil quality, carbon sequestration and environmental benefits (Reicosky 2015; Haddaway *et al.* 2017), though perhaps less economically beneficial at least in the first years of farming as yields tend to be lower than with conventional agriculture (Vastola *et al.* 2017) – but with time this gap can narrow. The drawback of NT and CA is an increased use of herbicides that goes along with reduced tillage.

Examples of policy instruments include decreased fertilizer taxes and governmental subsidies to farmers that have adopted NT (Lankoski, Ollikainen and Uusitalo 2004). Within the DPSIR framework (Section 1.6), this policy approach is mostly aimed at the pressure, to implement new tillage technologies that cause minimum soil disturbance, improve soil water retention capacity and provide erosion control (Dumanski *et al.* 2006; Serraj and Sidique 2012). The long-term application of NT and CA practices depends greatly on economic viability for farmers, especially those in developing countries (Krueger 2012). They rely largely on government subsidies, in particular for the acquisition of agricultural machinery that is suitable for such farming. The International Food Policy Research Institute (IFPRI) projects a big gain associated with adoption of NT cultivation in South Asia and the Pacific as a whole – with up to 32 per cent higher yields of maize and 47 per cent for wheat as compared with baseline scenario (Rosegrant *et al.* 2014).

##### **Case study: no-tillage cultivation in Western Australia**

By the late 1970s, arable farming was severely challenged in Western Australia because of drought and soil compaction. Between the 1980s and early 1990s, Australian farmers attempted to identify ways of overcoming the negative consequences of the drought by implementing NT systems (Bellotti and Rochecouste 2014). With the seeming benefits of NT, the adoption rate among other farmers increased reaching around 80-90 per cent by 2008 (Bellotti and Rochecouste 2014). **Table 15.6** gives a summary of the assessment criteria.

The Australian NT implementation was rated effective in soil and water conservation, pest, diseases and weed control, as well as in plant nutrient availability. This is demonstrated in the New South Wales NT programme, where NT contributed to improvement in soil fertility, stabilization of soil acidity, as well as increase in soil organic carbon content (Bellotti and Rochecouste 2014).

**Table 15.6: Summary of the assessment criteria for NT implementation in Australia**

| Criterion                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | References                                                                  |
|-----------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------|
| <b>Success or failure</b>         | It is recognized that in Australia NT implementation leads to a profound improvement in soil water conservation, increasing the amount of soil water available for crop growth and nutrient uptake. New South Wales farmers adopted an NT programme as a strategy to stem soil nutrient losses from long-term conventional farming practices. The fertility of the soil at the sites improved considerably while soil acidity was stabilized. In addition, there was marked improvement in the organic carbon content of the soil. All these critical positive contributions of NT are key indicators for measuring success or failure.                                                                                                                                                                                                                                                                                                                                                                                     | Bellotti and Rochecouste (2014)                                             |
| <b>Independence of evaluation</b> | Bellotti and Rochecouste (2014) implemented independent evaluations of the NT programme from Australian No-Till farming associations in 2014.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | Bellotti and Rochecouste (2014)                                             |
| <b>Key actors</b>                 | The key actors of the Australia NT programme include farmers, Western Australian No Tillage Farmers Association and the Australian Government, which offered tax credit incentives to farmers practising NT agriculture as well as the farmers advisers                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                                                                             |
| <b>Baseline</b>                   | The International Food Policy Research Institute (IFPRI) projects a big gain associated with adoption of NT cultivation in South Asia and the Pacific. The Economics of Land Degradation Initiative reports positive data of NT technology implementation in Tajikistan. Nevertheless, for Australia these figures might be lower taking into account the adoption rate of NT technology. Therefore, the potential for expansion of NT in Australia is considered negligible.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | Rakhmon (2016)                                                              |
| <b>Time frame</b>                 | The introduction of the NT commenced between early 1960 and 1980, which was described as the awareness period. Subsequently, farmers experimented with NT techniques resulting in its rapid adoption and diffusion.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                                                                             |
| <b>Constraining factors</b>       | NT cultivation requires more nitrogen fertilizers for use, especially during the first 2-3 years of NT, which constitutes a serious constraint to farmers with poor access to inputs. The use of herbicides is also a principal requirement for any NT system. In many cases, the use of non-selective herbicides such as glyphosate is associated with NT systems. Extensive use of such herbicides may cause negative impacts on biodiversity and human health. For example, in Europe the future permission to use glyphosate as herbicide in agriculture is currently under heavy scrutiny because of its implications on biodiversity and even possible adverse effects on human health. If permission is not to be extended in the future, the adoption of NT systems might decrease. Future developments in precision agriculture as a new farming system that optimizes returns by reducing inputs enabled by big data technologies and new sensors may, however, allow for dramatic reductions of herbicide needs. | Trigo <i>et al.</i> (2009)                                                  |
| <b>Enabling factors</b>           | There are several enabling factors for NT adoption in Australia. These include the perceived need for change and the changing complexity of farming. This has helped farmers to quickly understand the skill requirements for the successful practice of NT and they were quick to respond to the skill requirements in the context of NT in Australia. NT systems are also understood as promising instruments for climate change adaptation in agriculture. This thinking has promoted the widespread adoption and support for NT farming among stakeholders.                                                                                                                                                                                                                                                                                                                                                                                                                                                             | Bellotti and Rochecouste (2014); Lal (2014); Rosegrant <i>et al.</i> (2014) |
| <b>Cost-effectiveness</b>         | Evidence shows that NT is cost-effective, with several soil improvement and agronomic advantages. It is noted that NT improves farm operating budgets. This can vary across locations. There is also some evidence in many areas that, under conditions of good management, NT and CA positively lessen yield variability across seasons, especially in areas with poor rainfall.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | Serraj and Sidique 2012; Swella <i>et al.</i> 2015                          |
| <b>Equity</b>                     | As far as introduction of NT farming requires large capital investments in new equipment, poor farmers are unlikely to be able to afford this technology. However, statistics show no difference in extent of NT implementation between states in Australia, thus proving affordability of the system for most (80-90 per cent) farmers. There are no losers in NT agriculture in the real sense of it. However, farmers are the main gainers. Under NT agriculture, farmers have the opportunity to intensify cropping as much as possible due to the absence of fallowing in the NT as a CA practice.                                                                                                                                                                                                                                                                                                                                                                                                                     | Bellotti and Rochecouste (2014)                                             |
| <b>Co-benefits</b>                | NT practices enhance easy management of crop, soil and water conservation and improvements in crop yield, as well as saving of energy, cost and time, and therefore generally contribute to intensification of agriculture. The co-benefits of NT in this context include the farmers, governments and the general public that benefits from increased food production and sustainability of land resources and the environment.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | Giller <i>et al.</i> (2015)                                                 |
| <b>Transboundary issues</b>       | NT transboundary issues is in the areas of its contribution to reduction of global warming. NT contributes to reduction in albedo in cropland areas and thus has great potential for global cooling and reduction of global warming. NT also reduces the emission of nitrous oxide (N <sub>2</sub> O), which is a potent greenhouse gas, by as much as 40-70 per cent, depending on rotation.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | Wallheimer (2010); Omonode <i>et al.</i> (2011)                             |
| <b>Possible improvements</b>      | NT farming is suggested to be compatible with other technological innovations. IFPRI projections for 2050 suggests testing the following combinations of schemes: (i) NT + water harvesting; (ii) NT + precision agriculture; (iii) NT + heat tolerance; and (iv) NT + drought tolerance. In wetter regions such combinations could compensate some decline of yields reported for areas under NT.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | Rosegrant <i>et al.</i> (2014)                                              |

### 15.2.5 Responsible food policy systems to minimize food waste and promote stakeholder networking

The current food system is causing the potentially irreversible depletion of soils, water and biodiversity towards an irrecoverable degree (UNCCD 2017a, see Section 4.4.3). This also brings increased inequalities in accessing sufficient, fresh and healthy food, as well as a growing epidemic of (mal) nutrition-related illnesses, such as obesity, diabetes and heart disease (Rush and Yan 2017).

One attempt to address these challenges brought about the development of urban food policies aimed at integrating food issues and waste (Campoy-Muñoz, Cardenete and Delgado 2017), which in turn could reduce the pressure on land. It is estimated that 30 per cent of all food produced is wasted (FAO 2018); in the European Union alone, 88 million (metric) tons of food are lost annually (Stenmarck *et al.* 2016), amounting to a cost of €143 billion. Much of this loss comes from heavily populated urban areas. Hence, if losses were diminished more land would be available for environmentally friendly agricultural systems such as organic farming or agroecology with minor damages to the environment (Muller *et al.* 2017; Blakemore 2018). Moreover, almost all the biggest cities in Europe (Zdruli 2014) and around the world have expanded at the expense of the best soils suitable for crop production (Bren d'Amour *et al.* 2017).

The formal framing of urban food policy instruments was developed mostly in the last two decades. In the early 1990s, a few pioneering cities began to develop food strategies and food policy councils. Urban food policies represent actions on the part of city governments to deal with food-related challenges that require coordination between departments and policy areas, and the establishment of novel governance structures (International Panel of Experts on Sustainable Food Systems [IPESA-Food] 2017a).

Within the DPSIR framework (Section 1.6), this policy approach targets a set of natural resources drivers as well as rapid urbanization – to reduce unsustainable use of resources. Canada was one of the pioneering countries to develop an

#### Box 15.2: UNCCD Statement on food system

"Our food system has put the focus on short-term production and profit rather than long-term environmental sustainability. The modern agricultural system has resulted in huge increases while soil, the basis for global food security, is being contaminated, degraded, and eroded in many areas, resulting in long-term declines in productivity".

(UNCCD 2017a)

urban food policy in 1991 through the establishment of the Toronto Food Policy Council to advise the city on food policy issues, to serve as an advocate for community food security strategies, and to foster dialogue between stakeholders. Other urban food policies schemes are now being implemented around some European cities, such as Amsterdam, Ghent, Bristol, Edinburgh and London. A more detailed description is made in this chapter of the Milan Urban Food Policy Pact (De Cunto *et al.* 2017).

#### Case study: City collaboration on urban food good practices (Milan Urban Food Policy Pact)

A typical example of the city collaboration on urban food good practices is the Milan Urban Food Policy Pact (MUFPF), which came about in October in 2015. This is an international policy pact signed by a number of cities around the world committed to improving the sustainability of food systems and agricultural land uses in urban areas (Clinton *et al.* 2018). The current food regime may no longer be sustainable given its negative and potentially irreversible impacts on natural resources, which are currently on course to reach an irrecoverable degree (UNCCD 2017a). A transformation in food production distribution and consumption patterns is necessary to accomplish the needed changes in the current food regime and diminish its negative impacts on land and public health. Therefore, urban food policies have been conceived as having the potential to effect the needed changes in the global food sector both in terms of food safety and food security and natural resources use and management (Milan Urban Food Policy Pact 2018).

By 2030, the United Nations goal is to reach zero hunger (SDG 2). SDG 15 (life on land) is relevant to meeting the zero-hunger goal, but this can only happen with the active support of cities. The MUFPP, currently signed by 167 cities, commits signatories to develop sustainable policies, programmes and initiatives across all sectors that impact urban food systems in six thematic clusters: "(i) governance or ensuring an enabling environment for effective action; (ii) sustainable diets and nutrition; (iii) social and economic equity; (iv) food production including urban rural linkages; (v) food supply and distribution;

and (vi) food waste prevention, reduction and management" (Forster *et al.* eds. 2015). The MUFPP Framework for Action is voluntary and aims to accelerate city collaboration and enhance sustainable food systems while recognizing cities' diversity in terms of objectives and targets (Forster *et al.* eds. 2015). All these objectives are closely linked to environmental protection and biodiversity conservation (**Table 15.7**). A typical example of MUFPP outcomes is the case study in Mexico on sugar-sweetened beverages tax (Colchero *et al.* 2016), described below.

**Table 15.7: Summary of the assessment criteria on Milan Urban Food Policy Pact and its impacts in Mexico**

| Criterion                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | References                                                              |
|-----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------|
| <b>Success or failure</b>         | The MUFPP consolidates the role of cities as key actors in the global food system and promotes collaboration linkages among them. Two years after its launch at EXPO 2015 Milan Universal Exposition 'Feeding the Planet Energy for Life', as part of the landmark document Carta di Milano signed by United Nations Secretary-General Ban Ki-Moon on 16 October 2015, the pact is proving to be a useful instrument to promote collaboration among cities on food policies and helping them better implement land-use planning and enhanced environmental sustainability. | European Association for the Study of Obesity (2015)                    |
| <b>Independence of evaluation</b> | Although there is no evidence yet of the implementation of an impact assessment of the Milan Urban Food Policy Pact, one of the foremost independent impact evaluations of it was implemented in Mexico.                                                                                                                                                                                                                                                                                                                                                                   | Colchero <i>et al.</i> (2016)                                           |
| <b>Key actors</b>                 | The key actors in the MUFPP include the city mayors who signed the pact, and the civil society organization in the cities, private sector and research communities.                                                                                                                                                                                                                                                                                                                                                                                                        |                                                                         |
| <b>Baseline</b>                   | Available data shows that as much as 43 gallons of soft drinks are consumed per capita per year in Mexico. In addition, Mexican schoolchildren between the ages of 5 and 11 years consumed 20.7 per cent of energy drinks with about half of them sugar-sweetened, while the majority (64 per cent) of Mexican adults are overweight, 28 per cent obese and 11 per cent of Mexicans have type 2 diabetes.                                                                                                                                                                  | Flores <i>et al.</i> (2010); Bronwell <i>et al.</i> (2011); WHO (2015)  |
| <b>Time frame</b>                 | This initiative was launched in January 2014 by the Mexican Government and the independent evaluation was conducted in 2016.                                                                                                                                                                                                                                                                                                                                                                                                                                               |                                                                         |
| <b>Constraining factors</b>       | The constraining factors as identified by the Pact include the governance system within some cities with weak capacities of institutions and government departments, as well as poor stakeholder participation at the city level. Another constraining factor is the divergent cities policies that affect municipal authority or jurisdiction.                                                                                                                                                                                                                            | Forster <i>et al.</i> eds. (2015)                                       |
| <b>Enabling factors</b>           | The key enabling factors of the MUFPP implementation in Mexico are the evidence-based results framework of the Pact as well as availability of funding.                                                                                                                                                                                                                                                                                                                                                                                                                    | IPES-Food (2017b)                                                       |
| <b>Cost effectiveness</b>         | Thavorncharoensap (2017) examined the cost-effectiveness of obesity prevention and control through beverages taxes. Results showed that beverages taxes are a relevant and cost-effective measure for prevention and control of obesity. A few city cases reveal some techniques or actions that would result in cost-effective policies. These include microgardens, multiple cooperative start-ups, mobile apps, family shops, popular restaurant programmes and the promotion of urban agriculture.                                                                     | Forster <i>et al.</i> eds. (2015); FAO (2017); Thavorncharoensap (2017) |
| <b>Equity</b>                     | Six recommended actions are promoted for social and economic equity: (i) the use of social protection mechanisms such as cash and food transfers to vulnerable populations to increase access to food; (ii) reorientation of school feeding programmes to provide healthy food; (iii) promotion of decent employment; (iv) encouragement and support for social and solidarity economic activities; (v) promotion of networks and support for grass-roots activities; and (vi) promotion of participatory education, training and research.                                | Forster <i>et al.</i> eds. (2015)                                       |
| <b>Co-benefits</b>                | The co-benefits of the policy include local residents who receive support from the city government in many aspects of everyday life, including increased green areas and biodiversity, promotion of local economy that creates jobs, solidarity among inhabitants, better quality food, upgrading of abandoned areas, waste recycling and management, and the creation of a diverse urban landscape for recreation. Furthermore, the policy also dealt successfully with the heat waves and islands inside the city.                                                       | Forster <i>et al.</i> eds. (2015)                                       |
| <b>Transboundary issues</b>       | This network has the capacity to convene local governments and enhance their role in a multilevel governance structure providing a multi stakeholder platform for communication and exchange of successful implemented policies.                                                                                                                                                                                                                                                                                                                                           | Cinzia and Licomati (2017)                                              |
| <b>Possible improvements</b>      | There are gaps in certain critical areas, including the need for improvement in the level of collaboration among key government departments in the implementation of the Pact, policy coherence and the inclusion of all critical stakeholders in the implementation of the food policy.                                                                                                                                                                                                                                                                                   | Forster <i>et al.</i> eds. (2015)                                       |

The MUFPP has implications for the environment, economy, social equity and health of urban populations, and their linkage with rural and urban agriculture. An increasing number of cities are involved in this initiative and many more are expected to join the effort. The third Annual Gathering and Mayors' Summit of MUFPP was held in Valencia, Spain in October 2017 involving more than 400 mayors, experts and city delegates. They called on United Nations agencies to recognize their role in shaping a sustainable food system and create a better living environment inside and outside the cities. The policy efficiency of the Pact in Mexico is reflected with increased awareness among the local people on the health consequences of excess use of sweetened soft drinks and the need to return to traditional food systems.

## 15.3 Indicators

Land management is explicitly targeted in SDG 15.3 and also has many interconnections with other SDGs, namely SDGs 1, 2, 3, 6, 7, 11, 12 and 13. The SDGs include a total of 244 indicators for which general agreement was reached. Based on data availability and relevance to land and soil policies, three SDG indicators stand out as most relevant for this chapter (Table 15.8):

1. Proportion of land degraded over total land area (Indicator 15.3.1),
2. Terrestrial protected areas as a percentage of total land area (Indicator 15.3.2), and
3. Ratio of land consumption rate to population growth rate (Indicator 11.3.1).

**Table 15.8: Indicators for assessing land policy effectiveness and for measuring the progress towards the achievement of global environmental goals**

| Indicator                                                       | Rationale for selection                                                                                                                                                                                                | Addressed in Part A: Yes/No How:                                                                                                       | Addressed in the case studies: Yes/No Which                                                                                                                                       | Connection with the SDGs or MEAs                                                     | Data sources                                                                                                                                                                                                                                                                                               | Causal chains to policies and other variables impacting the indicator                                                                                                                                                                                                                             |
|-----------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1. Proportion of land degraded over total land area             | SDG indicator 15.3.1: There is scientific and political consensus as well as precedence and agreement.                                                                                                                 | Yes. Section 4.4.3 on the food system; a 'box' on the Syrian Crises <b>Box 9.4</b> : Jordan faces a combined refugee and water crisis. | Yes<br>2.2 Setting threshold values<br>2.3 Planning and compensation<br>2.4 Funding programme plus setting standards for best practice management<br>2.4 Provision of consultancy | It is an indicator for SDG 15. 'Land degradation' is defined and discussed in UNCCD. | See following sources on land degradation: Gibbs and Salmon 2015; Le, Nkonya and Mizarbaev 2016. FAO has the Global Land Degradation Information System (GLADIS); Sustainable Development Solutions Network [UNSDSN] (2014) noted that data on degraded land has been 'patchy'. Also see UNCCD's metadata. | IPBES (2018a) indicates that proportion of degraded land over total land continues to increase, mostly due to lack of policies or poor implementation.                                                                                                                                            |
| 2. Terrestrial protected areas as percentage of total land area | SDG indicators 15.1.2 and 15.4.1: There is scientific and political consensus as well as precedence and agreement.                                                                                                     | No                                                                                                                                     | No                                                                                                                                                                                | SDG indicators 15.1.2 and 15.4.1.                                                    | The United Nations List of Protected Areas (International Union for Conservation of Nature [IUCN] 1994; IUCN 1998; Chape <i>et al.</i> 2003) are available online. There is also the World Database on Protected Areas. UNEP-WCMC has the Protected Planet Report. See (United Nations 2018).              | Policies for the protected areas had overall positive impacts, especially in developed countries, with less pronounced results in the rest of the world.                                                                                                                                          |
| 3. Ratio of land consumption rate to population growth rate     | Since land consumption is the strongest and mostly irreversible form of land degradation, its decoupling from population growth is the core step in maintaining land, also in relation to the nexus to the other SDGs. | Yes. Section 2.2                                                                                                                       | Yes. 2.1 Stakeholder Network creation                                                                                                                                             | SDG indicator 11.3.1                                                                 | UN-Habitat for all countries of the world. Data for more than 300 cities are monitored by The City Prosperity Initiative, Lincoln Institute, University of New York and UN-Habitat.                                                                                                                        | Globally, land cover today is altered principally by direct human use. Evidence from a study on 120 cities revealed a three-times faster growth of urban land cover compared to the growth of urban population. Other variables affecting the indicator are land degradation and crop production. |

These were used in the assessment of policy effectiveness and for measuring progress towards internationally agreed environmental goals with special reference to land and soil.

### 15.3.1 Indicator 1: Proportion of land degraded over total land

The expansion of human economic activities and the competing interest for land resources have dramatically increased the pressure on land and on terrestrial ecosystems (Figure 15.3) and in some cases accentuated political conflicts at local level (Organisation for Economic Co-operation and Development [OECD] 2017). Estimates of global land degradation show that about 25 per cent of all land is degraded, 36 per cent is slightly or moderately degraded, while 10 per cent is improving (FAO 2011; IPBES 2018b). The unit of measurement of this indicator is the area (ha or km<sup>2</sup>) of land that is degraded divided by the total land (UNCCD 2017b). This indicator is measured by adding all those areas that are subject to change, and whose conditions are considered as negative by national authorities when measuring and evaluating each of the following three sub-indicators:

- ❖ land cover and land cover change,
- ❖ land productivity, and
- ❖ carbon stocks above and below ground.

The indicator is linked to several targets and commitments that have been agreed by global, regional and national governments to halt and reverse land degradation and restore degraded land (IPBES 2018b). These include, for instance, the Aichi Biodiversity Targets, the Bonn Challenge and related regional

initiatives (e.g. 20x20, African Forest Landscape Restoration Initiative [AFR100] 2018), and SDG target 15.3.

The indicator addresses the nature of land degradation, which is expressed as “the reduction in the capacity of land to provide ecosystem goods and services over a period of time for its beneficiaries” (Nachtergaele *et al.* 2011; Zdruli 2014). Land degradation has direct impacts on the capacity for net biomass primary production, but socioeconomic factors play a major role in its occurrence – such as the link between urbanization and its related soil and air pollution (Prasad and Badarinh 2004; Seto, Güneralp and Hutyra 2012). In other cases, socioeconomic factors have hindered efforts to cope with land degradation (Lubwana 1999; Chasek *et al.* 2011). This is the case of urban sprawl or the expansion of solar panels promoted by renewable energy policies and lack of well-defined land-use planning guidelines that have accelerated these types of land-use changes at the expense of fertile soils that otherwise should be used for food production or preservation of nature-based contributions to people (Diaz *et al.* 2018).

Policy effectiveness in either halting or reversing the expansion of degraded areas over total land areas have produced limited results; globally, land degradation remains one of the most important degradation processes with huge consequences for food security, environmental consequences and threats to livelihoods (IPBES 2018b).

Figure 15.3 emphasizes the role of soil carbon sequestration as an important indicator directly linked to soil fertility and climate change mitigation. The 4 per 1000 Initiative is promoting carbon accumulation in the world soil at a rate of 0.4 per cent

Figure 15.3: Trends in land degradation and restoration worldwide

Source: World Bank (2018, p. 59).

per year to stop CO<sub>2</sub> increase in the atmosphere which is major contributor to climate change. The initiative intends to reach its goals by implementing the principles of conservation agriculture and agroecology. The figure shows expansion of desertification in the Sahel, deforestation in Latin America and positive results in land restoration in southern China.

### 15.3.2 Indicator 2: Terrestrial protected areas as a percentage of total land area

Since the mid-1990s, growing concerns over environmental degradation have led to the current emphasis on the roles that nature plays in maintaining societies (Butchart *et al.* 2015; Diaz *et al.* 2018). In recognition of the significance of this, 193 Parties of the Convention on Biological Diversity (CBD) adopted the 20 Aichi Targets to be met by 2020. Aichi biodiversity target 11 is of particular relevance and commits to a 1.6 per cent increase (from 15.4 per cent to at least 17 per cent) in protected areas by 2020 (CBD 2010). This could also contribute to reducing the loss of natural habitats (target 5), reducing human-induced species decline and extinction (target 12), and maintaining global carbon stocks (target 15). Countries have since agreed on the SDGs' targets (United Nations 2015) for 2020 and beyond, and this is likely to drive the agenda on protected terrestrial areas in the coming decades (Allen *et al.* 2016). SDG 15 specifically refers to land resources and their management.

This indicator measures the proportion of terrestrial protected areas as a share of the total land area expressed as a percentage (United Nations 2015). The purpose of the indicator is to represent the extent to which terrestrial areas that offer ecosystem value in terms of conserving biodiversity, cultural heritage, scientific research, recreation and other valuable uses are protected, in their diversity and integrity, from unsustainable land uses (United Nations 2015).

The indicator is calculated using all the nationally designated protected areas recorded in the World Database on Protected Areas (WDPA) (United Nations Environment

World Conservation Monitoring Centre 2018). World Bank (2017) data show that the surface area of protected areas for the period 1990-2014 increased from 8.2 per cent to 14.8 per cent, indicating a positive trend reflecting the implementation of national and international policies for them (Figure 15.4).

Governance of protected areas, in particular primary forests, is particularly relevant because evidence points to the impacts of agricultural output prices on deforestation rates both inside and outside of protected areas (Deiro and Escobar 2012). Assunção, Gadour and Rocha (2015), in a study in the Amazon, found high correlations between deforestation rates and agricultural output prices, while Deiro and Escobar (2012) point out that "between 1981 and 2010 an area of 45,000,000 hectares was downgraded or lost with almost 70 per cent of cases occurring since 2008". The authors (Deiro and Escobar 2012), however, conclude that changes in conservation policies implemented between 2004 and 2008 significantly contributed to the curbing of deforestation rates.

Location is another key influencing factor affecting protected areas. Joppa and Pfaff (2009) note that "the positioning of protected areas is not random; they are often located in areas that are inaccessible or unsuitable for agriculture, in remote and topographically challenging areas without transport links, such that they are unlikely to be under pressure from the developmental drivers of land use change".

In general, there is scientific and political consensus, as well as precedence and agreement, on this indicator. However, evidence of the impacts of market prices, management effectiveness and factors specific to other sites have since led to the proposal to incorporate indicators that aid in the measurement of protected area conditions and/or management effectiveness, including more equitable management and representative indicators of spatial coverage (e.g. forest area as a percentage of land area).

Figure 15.4: Terrestrial protected area as a percentage of total land area per country (1990-2014)

Source: World Bank (2018, p. 59).

### 15.3.3 Indicator 3: Ratio of land consumption rate to population growth

In 2016, about 54.5 per cent of the global (human) population lived in urban areas and by 2030, the United Nations predicts that 60 per cent of the global population will be urban (United Nations 2016a). The total increase in urban population between 2000 and 2020 is estimated at 1.48 billion, of which 1.35 billion will be concentrated in less-developed regions (United Nations 2012). As population growth increasingly consumes available land, cities expand far beyond their formal administrative boundaries and urban sprawl is visible around them (United Nations Human Settlements Programme [UN-Habitat] 2017).

Land consumption rate is computed as a function of: (a) "The expansion of built-up area which can be directly measured; (b) the absolute extent of land that is subject to exploitation by agriculture, forestry or other economic activities; and (c) the over-intensive exploitation of land that is used for agriculture and forestry" (United Nations 2015). Population growth rate shows the increase of population in a country during a certain period, typically one year, expressed as a percentage of the population at the start of that period (World Bank 2017). **(Figure 15.5).**

The ratio of land consumption rate to population growth is a critical indicator that is closely connected with multiple SDGs. More directly, it is tied in with SDG 11, "Make cities and human settlements inclusive, safe, resilient and sustainable".

The changes in land consumption are largely driven by increases in transport infrastructure, poor urban and regional planning, and land speculation (UN-Habitat 2015). This in turn negatively impacts on the environment (per capita resource use and greenhouse gas emissions). For example, for every 10 per cent increase in urban sprawl, there is a 5.7 per cent increase in per capita CO<sub>2</sub> emissions and a 9.6 per cent increase in per capita hazardous pollution. It also increases socioeconomic and spatial inequalities. For instance, 30 per cent of the global urban population (880 million people) lived in slum-like conditions in 2014; in sub-Saharan Africa, that proportion was 55 per cent (United Nations 2016b).

While evidence shows that poor spatial planning is one of the main factors leading to urban sprawl, effective policymaking is central to managing land consumption (Rosni and Noor 2016). Many governments rely on policies such as land-use restrictions (e.g. urban growth boundaries and minimum-lot zoning); price-based policies such as property taxes (Gyourko and Molloy 2015; Glaeser and Gyourko 2017); and other regulatory systems composed of zoning ordinances, subdivision regulations and building codes, for controlling urban sprawl. Feng *et al.* (2016) conclude that the implementation of land-use planning policy in China played a major role in ensuring the lowest effective rate of change of sprawl. The potential of restoring and reutilizing former industrial and otherwise used land (brownfields) for mitigating land consumption is still underexplored in land planning and policies (Tobias *et al.* 2018).

**Figure 15.5: Ratio of land consumption rate to population growth rate by region and period (1990-2015)**

Source: UN-Habitat (2015).

Given the high rates of land consumption in the European Union – 275 ha of agricultural and natural habitats converted to urban sprawl and other forms of land take per day – the EU has endorsed a No Net Land Take by 2050 policy that intends to reduce land consumption throughout the Union, giving priority to greening areas and ecological corridors (University of the West of England, Science Communication Unit 2013).

Seto, Güneralpa and Hutya (2012) state that varying causal factors make it difficult to observe this indicator on an international scale. The lack of standardized procedures in the delineation of spatial units and recognition of administrative boundaries lead to spatial inconsistencies (United Nations 2018). UN-Habitat therefore proposed a minor revision of indicator 11.3.1 to “Ratio of land consumption rate to population growth rate, including the term *Efficient land use*”, where if the ratio is equal to or smaller than 1 it is qualified as efficient.

Other alternate indicators proposed include:

- ❖ “Resources per capita invested in human settlement per km<sup>2</sup>” (by UNCDF)
- ❖ “Percentage of cities with direct participation structure of civil society in urban planning and management, which operate regularly and democratically” (by United Nations Statistical System Organizations)
- ❖ “Ratio of land consumption rate to urban population growth rate at comparable scale” (by UNFPA).

## 15.4 Conclusions

Across the globe, while different land policies and initiatives have been adopted and implemented, it is however difficult to attribute progress in the thematic area to specific policy approaches for several reasons.

Firstly, the transboundary nature of land and its resources (Sikor *et al.* 2013) hinders the assessment of policy effectiveness. Many land resources such as forests cannot be managed at state level alone because they straddle international borders. Activities in one country often have effects on neighbouring countries’ land policies and initiatives. This hinders attribution of progress to a specific policy approach with respect to sustainable management of land and its resources (Creutzig 2017). Land tenure is also a constraining factor and global land acquisitions, or ‘land grabbing’, amounts to more than 42 million ha, mostly in Africa. Food-importing countries have accelerated their acquisitions to enhance food security globally.

Closely related to the above are the challenge of teleconnections. Demand for food in some places generates land uptake in others; for instance, Africa is a net contributor to the food needs of Europe (Bergmann and Holmberg 2016). In this context, sustainable land management policies in a country can be positively (or otherwise) impacted by demand from another country, which also makes it difficult to attribute progress to a specific policy approach. The regenerative capacity of land resources is another major obstacle to attribution of land policies. Food, water, forests and wildlife are all renewable resources. With or without any policy framework,

some land resources such as forest systems can regenerate themselves, making attribution to specific forest conservation policy difficult.

The World Bank (2006) provides a set of principles, “where land and resource management policies have been successful” there is:

1. Local community participation in all aspects of the programme
2. Public support for private investment in soil and water conservation
3. Improvement and maintenance of roads
4. Sound macroeconomic management that does not discriminate against agriculture and natural resources
5. Robust local capacity-building by non-governmental organizations and other cooperative-type projects, and
6. Consistent efforts over at least a decade by concerned governments to increase not only land productivity but also awareness of environmental problems and possible solutions at local levels.

Some of these are conditions addressed in the case studies of this chapter. However, there are two emerging policy approaches which hold out promise for the future. The first policy approach involves the use of economic incentives to deal with environmental issues related to land, as the China case study (Section 15.2.2) demonstrates.

The second approach is the Sustainable Intensification of Land Use and Integrated Resource Management (Garnett *et al.* 2013), despite the criticism about the overall benefits of the agricultural intensification concept (Rasmussen *et al.* 2018). This approach is best described by technological advancements that ensure increases in crop production through implementation of sustainable land and water practices, such as conservation agriculture and no-tillage cultivation, as described in the Australia case study (Section 15.2.4) as well as combined cropping systems such as legumes and cereals; agroforestry, agroecology (World Bank 2006) and regenerative agriculture. One of the key lessons learned from the case studies is the importance of a robust institutional framework for policy implementation.

Across the case studies, the establishment of institutional and administrative capacities for policy implementation underpins the success of most of the key policies. The indicators are relevant to key interconnected international goals such as the SDGs and provide evidence of progress towards meeting the policy objectives. For instance, Indicator 2 on terrestrial protected areas as a percentage of total land area is connected to Aichi Biodiversity Targets 13, 11 and 5 and is also relevant to SDG 15 and its respective targets.

The case studies also indicate that evaluation of policy effectiveness in most cases has been commissioned by external stakeholders, while national governments that are often involved in policy design have not shown serious interest in policy evaluation. Land policy evaluation is important as it will provide significant lessons that can be useful in the refinement of policies and implementation of strategies.

One obvious gap is the fact that most national land policies are not linked to international goals. This is important, especially from the point of view of the SDGs, when viewed against the background that the implementation of such policies will have little or no contribution to the attainment of international goals. The Kyoto Protocol did not even mention relation to the role

of land and soil in climate change dynamics. When national governments ratify international conventions, it is important that these are backed up with relevant national policies accompanied by baseline indicators to track progress towards reaching policy goals.

# Chapter 16

## Freshwater Policy

**Coordinating Lead Author:** Peter King (Institute for Global Environmental Strategies)

**Lead Authors:** Erica Gaddis (Utah Department of Environmental Quality), James Grellier (European Centre for Environment and Human Health, University of Exeter), Anna Maria Grobicki (Food and Agriculture Organization of the United Nations [FAO]), Rowena Hay (Umvoto), Naho Mirumachi (King's College London), Gavin Mudd (RMIT University), Farhad Mukhtarov (Erasmus University Rotterdam), Walter Rast (Meadows Center for Water and the Environment, Texas State University),

**GEO Fellows:** Beatriz Rodríguez-Labajos (Universitat Autònoma de Barcelona), Jaee Sanjay Nikam (Arizona State University), Patricia Nayna Schwerdtle (Monash University)

## Executive summary

**Addressing drivers and pressures is the key to making effective freshwater policy.** This can be achieved through regulatory command-and-control mechanisms, subsidies, supporting investments and enabling actors, but there is also value in process-based innovative approaches such as experimentation, learning and voluntary reporting. {16.2.1, 16.2.4}

**Policy coherence and synergy are needed to address the water-food-energy-health-ecosystems nexus.** Policy mixes are typically adopted to meet demands across multiple sectors and to manage implications outside the freshwater policy sphere. Intricate linkages among water quality and quantity, agriculture, human health, ecosystems and energy systems require that freshwater policy is developed with this nexus placed centre-stage. Achieving policy coherence and synergy are important benefits of this integrated thinking, as water policies influence policies in other sectors, especially agriculture and energy. {16.2.1, 16.2.2}

**Much freshwater policy is highly context dependent, yet a variety of freshwater policy types and governance approaches can diffuse to fit diverse local contexts.** Governance approaches and policy types are diverse. The design, implementation and evaluation of these policies require that institutional structures, economic resources and other enabling factors are in place. {16.1, 16.2.3, 16.2.5}

**There is scope for freshwater policy to better consider co-benefits to ecosystems and human health.** Changes to water quality and quantity through interventions such as infrastructure investment and natural hazards requires consideration of direct threats to human health but capitalizing on potential co-benefits is not yet widely practised. {16.1, 16.2.2, 16.3}

**Policy effectiveness draws attention to the role of citizens, the private sector and non-governmental bodies, in particular through participatory processes.** Implementing integrated water resources management (IWRM) is a participatory process, based upon intersectoral coordination and greater engagement of non-governmental actors. Collaborative efforts are required to involve the private sector and non-governmental organizations, or local governments and citizens. Stakeholder engagement is a long-term process and requires investment in supporting stakeholder relationships. Institutions should be designed to enable inputs into decision-making from

these relationships rather than treating them on an ad hoc basis. Devolution of water governance requires supporting investments, capacity-building and sustained long-term efforts in raising awareness. Exchanging knowledge at the subnational level enables effective stakeholder involvement. {16.1, 16.2.1, 16.2.2, 16.2.5}

**Evaluating policy effectiveness is enhanced by consistent and transparent reporting and systematic monitoring.** For policy effectiveness, defining baseline conditions is needed prior to implementation for comparison and lesson learning. Standardization of sustainability reporting, development of national reporting mechanisms, and the use of knowledge hubs for scientific reporting have proven useful {Sections 16.2}. Reporting and monitoring helps tracking of Sustainable Development Goal (SDG) progress at both national and global levels and helps identify causal relations of specific policy interventions. {16.3.1, 16.3.2}

**While policy approaches become further integrated and complex, there is an ongoing need to address basic environmental clean-up and the reversal of damaging legacies.** Even in developed economies, regulation, technical fixes and investments are required to continually improve practices of water use and prevent water quality degradation {16.1}. Policies may need to be revised to change the direction of trends in water use. {16.6.1}

**Environmental and freshwater policies can be effectively driven by the consideration of social issues, especially equity and health.** Disparities within a country or between developed and developing countries can motivate national as well as global efforts for addressing access to water and sanitation services, underpinning the human right to water and sanitation. {16.2.3, 16.2.5}

**Transformative potential can be seen in effective and innovative freshwater policies that benefit both people and planet.** The environmental flows approach carries transformative potential, as it is a way of assessing quantitatively the water needs of the river as a living system, and of balancing these water requirements against the water requirements of various economic sectors. As more rivers are assessed in this way, environmental flows become a fundamental building block of river basin management and governance, leading to the integration of management of water and landscapes through the entire catchment. {16.2.1}

## 16.1 Introduction

The Millennium Development Goals (MDGs) motivated countries to tackle issues relating to sustainable access to safe drinking water and basic sanitation. The Sustainable Development Goals (SDGs) now present an even more ambitious global framework within which the multidimensional concerns of availability, quality, use and governance of water can be addressed. Chapter 9 in Part A identifies a broad set of policies that have been used across the world to address specific aspects of targets defined in SDG 6. These include generic policy approaches such as market instruments, regulatory programmes, monitoring, capacity-building, as well as water specific interventions such as desalination and conjunctive use of surface and groundwater.

Policies highlighted in Section 9.9 demonstrate the increasing attention given to larger spatial scales, including considerations beyond the scale of the river basin, as exemplified in the case of virtual water trading, and the incorporation of multiple institutional scales not confined to the national level. Accordingly, this analysis of freshwater policy effectiveness begins by focusing on multiple water uses within policies and the multi-sectoral considerations of given policy approaches and highlights the strengths and weaknesses of policies addressing the nexus that connects water, food, energy, climate, ecosystems and health.

## 16.2 Key policies and governance approaches

There is traction in policy communities to address the water-food-energy nexus so that freshwater policy approaches can be sensitive to the ways in which the hydrological cycle, ecosystems, food and energy systems are connected. Efforts to meet this need are, however, relatively new and must tackle the challenge of engaging multiple spatial, temporal and governance scales. Consideration of equity aspects, so that injustices in procedure and outcomes are averted, plays an important part in the discussion of effectiveness of policies addressing this nexus. Through case studies and an analysis of indicators related to the SDGs, this chapter shows how the nexus concept matters in relation to policy effectiveness and cost-effectiveness. The case studies collectively demonstrate

national and transboundary water policies from around the world that have had moderate successes and implementation challenges in dealing with the following:

- ❖ Empowerment of local water managers while maintaining consistent protections across countries and transboundary water basins;
- ❖ Design and operation of dams to minimize impacts on ecosystems while providing benefits to human health, agriculture and energy as well as considering environmental flows and the use of adaptive management;
- ❖ Reform of flood risk management policy in line with integrated water resources management (IWRM) with greater responsibilities given to local authorities;
- ❖ Provision of basic water services to poor communities in water-scarce regions; and
- ❖ Improvement of the consistency and transparency of sustainability reporting conducted by the private sector.

In addition, three policy-relevant indicators on access to water and sanitation and on water withdrawals are reviewed. These indicators represent another way in which global water policy can be assessed.

Collectively, the case studies and indicators demonstrate the mix of policy instruments and clusters that have evolved to manage nexus concerns in an integrated way, which represents a shift from decision-making by a singular governmental authority to governance through sets of rules, principles and procedures involving various stakeholders.

Policy approaches and case studies addressed in this chapter (**Table 16.1**) are linked to the policy typology of Chapter 10.

### 16.2.1 Regulatory frameworks for transboundary water quality management

Transboundary water bodies are shared by two or more States. The management of these shared rivers, lakes or aquifers relies on multilateral coordination and institutional development. International agreements between States are formal arrangements for transboundary water governance.

**Table 16.1: Policy approaches and case studies**

| Governance approach                                                                        | Policy instrument(s)                                                         | Case study                                                                                                                                                      |
|--------------------------------------------------------------------------------------------|------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Command and control; enabling actors; supporting investments                               | Water quality goals coordinated through a binational transboundary agreement | North American Great Lakes Water Quality Agreement                                                                                                              |
| Enabling actors; command and control                                                       | Environmental flow                                                           | Adaptive management of Glen Canyon Dam                                                                                                                          |
| Economic incentives; command and control                                                   | Collaborative institutional design                                           | Disaster Risk Reduction Flood Risk Management, United Kingdom of Great Britain and Northern Ireland – ‘Making Space for Water’ and Flood Risk Management Policy |
| Command and control; economic incentives; supporting investments                           | Water pricing and free provision of basic water supply                       | Free basic water policy, South Africa                                                                                                                           |
| Promotion of innovation; enabling actors; convincing consumers, employers and stockholders | Standardization of sustainability reporting                                  | Mining – sustainable water                                                                                                                                      |

In particular for transboundary rivers, agreements have become more comprehensive and more numerous over time, reflecting an integrated approach to managing shared rivers and lakes (Giordano *et al.* 2014). By 2007, there were 250 freshwater treaties and 30 additional treaties are established every decade (Giordano *et al.* 2014), mostly focusing on water quality and the environment. However, obligations, responsibilities and enforcement mechanisms to address water quality have typically been left undefined (Giordano *et al.* 2014). Regulatory agreements have tended to exclude direct data- and information-exchange mechanisms (Gerlak, Lautze and Giordano 2011). These trends combined indicate that while water quality may be regarded as important, specific policy interventions have been hard to establish.

River basin organizations (RBOs) for transboundary water bodies can be vehicles of treaty implementation. In general, the main functions of RBOs are (i) data gathering, monitoring and regulation; (ii) river basin planning; and (iii) development of infrastructure and facilities (Global Water Partnership [GWP] 2017). Many RBOs are guided by IWRM principles that seek to achieve efficiency, equity and ecological sustainability, while also addressing water quality and quantity issues. Within the Drivers, Pressures, State, Impact, Response (DPSIR) framework (Section 1.6), this institutional approach is aimed at identifying pressures that cause water quality degradation, reasonable and equitable water use and ecosystem concerns.

The success of agreements and frameworks requires scrutiny as institutional development does not guarantee water quality improvement and prevent free-riding (Bernauer and Kuhn 2010), and effectiveness of cooperation can be questioned (Mirumachi 2015).

#### **Case study: The North American Great Lakes Water Quality Agreement**

In response to pollution of the Great Lakes Basin (Thornton *et al.* 1999), the United States of America and Canada, under the umbrella of the Boundary Waters Treaty (*Boundary Waters Treaty* 1909), signed the Great Lakes Water Quality Agreement in 1972 (*Great Lakes Water Quality Agreement* 2012).

With a population of more than 30 million people (United States Environmental Protection Agency [US EPA] 2017), the Great Lakes Basin receives substantial inputs of point source and non-point source pollution from a large range of industrial, agricultural, forestry and urban sources (Marvin, Painter and Rossmann 2004). Pollutants of particular concern in terms of impact on ecosystems and human health include biomagnifying metals such as mercury and persistent organic pollutants (POPs), including polychlorinated biphenyls (PCBs), polycyclic aromatic hydrocarbons (PAHs), polychlorinated naphthalene (PCNs), organochlorine pesticides (OCPs), polybrominated diphenylethers (PBDEs) and perfluorinated chemicals (PFCs) (Helm *et al.* 2011). Another danger to the ecosystem comes from invasive species and harmful algal blooms and eutrophication (Smith *et al.* 2015).

The current agreement comprises annexes addressing a range of Great Lakes water quality issues, including areas of concern, lake-wide management, pollution control, ecosystem maintenance and climate change impacts. It encompasses a range of policy clusters involving federal, state and local institutions, facilitation of cooperative actions (both regulated

and voluntary), with each country contributing actions from their domestic programmes, policies and resources.

The International Joint Commission (IJC) is a permanent, binational institution for dispute resolution. Under the Treaty from 1909, the IJC was given powers to apply governing principles for water use and the arbitrational power to resolve disputes (Krantzberg and De Boer 2008). Additionally, the federal governments of the two countries periodically request IJC to investigate specific boundary water issues (Findlay and Telford 2006; McLaughlin and Krantzberg 2012). Accordingly, the IJC conducts semi-annual meetings under the Boundary Waters Treaty, with the scope of these meetings covering a full range of boundary issues across the Canada-United States of America boundary ([http://www.ijc.org/en/\\_meetings\\_minutes](http://www.ijc.org/en/_meetings_minutes)). Under the Great Lakes Water Quality Agreement, the IJC was given a reference unique to the Great Lakes – namely to provide advice and recommendations to government, and to report on progress in implementing the agreement. To this end, the Parties to the Great Lakes Water Quality Agreement (i.e. national governments) conduct semi-annual meetings specific to the implementation of the agreement (IJC 1980; IJC 1981; IJC 2001; IJC 2017).

Pursuant to the 1987 Protocol in the Great Lakes Water Quality Agreement, 43 ‘areas of concern’ were identified. These areas were found to exhibit severely degraded water quality and ecosystem health (12 in Canada, 26 in the United States of America and 5 shared). The environmental degradation is primarily a legacy of the past, attributable to industrial activities, agriculture, urban and rural run-off, municipal wastewater effluents, land-use planning and practices on urban and rural lands, all contributing to degraded water quality, contaminated river and lake sediments, and severely impacted fish and wildlife populations and habitats. **Table 16.2** presents our evaluation of the effectiveness of the Great Lakes Water quality Agreement.

**Table 16.2: Evaluation of the effectiveness of the Great Lakes Water Quality Agreement**

| Criterion                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | References                                                 |
|-----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------|
| <b>Success or failure</b>         | A total of seven areas of concern have been delisted (three in Canada; four in the United States of America). There are others considered areas of recovery, where actions have been completed and these areas are expected to be delisted soon.                                                                                                                                                                                                                                                                                                                                                                                                       | (US EPA 2017)                                              |
| <b>Independence of evaluation</b> | Progress is typically reported by the Parties and assessed by the International Joint Commission (IJC) on the basis of input from two major advisory boards (Great Lakes Water Quality Board and Science Advisory Board). The Water Quality Board provides policy advice and evaluation, and the Science Advisory Board provides scientific advice and evaluation. The IJC also publishes a triennial assessment report that reviews the progress of the Parties, summarizes public input on the Parties' progress report, and includes an assessment of the degree to which programmes are achieving the agreement's general and specific objectives. | United States National Research Council (1985); IJC (2017) |
| <b>Key actors</b>                 | The key actors are the governments of the United States of America and Canada, in collaboration with other jurisdictions that support implementation of the agreement. A key role of the IJC, in assisting the governments, is its assessment role.                                                                                                                                                                                                                                                                                                                                                                                                    | IJC (2017)                                                 |
| <b>Baseline</b>                   | The Parties have adopted nine General Objectives under the agreement that outline high-level ecosystem objectives towards which they are working. The Parties have also established a suite of nine indicators of ecosystem health, supported by 44 sub-indicators, to assess the state of the Great Lakes, and whether or not progress is being made towards achieving the General Objectives.                                                                                                                                                                                                                                                        | IJC (2017)                                                 |
| <b>Time frame</b>                 | The agreement became effective with its adoption by both governments in 1972, with the most recent amendment in 2012. It has provided the binational framework for both countries to work towards the restoration and protection of the Great Lakes for over 45 years.                                                                                                                                                                                                                                                                                                                                                                                 | US EPA (2017)                                              |
| <b>Constraining factors</b>       | Although public scrutiny of the progress of the Parties provides a powerful oversight role (e.g. through binational public webinars on substantive issues), there have been calls for a more inclusive discourse and an increased role for citizen engagement, particularly during renegotiation periods of the agreement. A shift from an ad hoc problem-resolution mindset to a more imaginative and strategic thinking approach has also been advocated.                                                                                                                                                                                            | Krantzberg (2012)                                          |
| <b>Enabling factors</b>           | Canada and the United States of America have the capabilities to meet the substantial policy, institutional, technical, financial and personnel obligations inherent in carrying out the objectives of the agreement. They have an ongoing system of plans for remedial action in the areas of concern and target an adaptive system of experimentation and learning in pursuing remedial work in regard to addressing the General Objectives of the agreement.                                                                                                                                                                                        | Hall, O'Connor and Ranieri (2006)                          |
| <b>Cost-effectiveness</b>         | Both countries depend on lake-derived ecosystem services that amount to US\$7 billion annually in economic activity related to recreational and commercial fishing alone. The basin-wide approach resulted in doubling the habitat of fish species at a cost of US\$70 million, whereas a less integrated approach of addressing only dams or only road crossings resulted in striking inefficiencies of 24 per cent and 88 per cent less habitat, respectively.                                                                                                                                                                                       | Southwick Associates (2008); Neeson <i>et al.</i> (2015)   |
| <b>Equity</b>                     | The governance of the Great Lakes includes approximately 120 Native American, First Nation and Metis rights holders, as well as low-income and minority people, which provides opportunities for collective management. Traditional knowledge and input from the community of First Nations in Swan Lake Marsh, Canada, was used for a project on wetland restoration and to plan guided activities in the past few years.                                                                                                                                                                                                                             | Hildebrand, Pebbles and Fraser (2002); Jetoo (2017)        |
| <b>Co-benefits</b>                | The agreement, in enhancing the quality of the water, created wealth in several forms, including increased recreational and commercial fishing (see 'Cost-effectiveness'), as well as increased recreational use and tourism. The main beneficiaries were riparian inhabitants living around the lakes and their basins, water sports and fishing enthusiasts, tourists and visitors.                                                                                                                                                                                                                                                                  |                                                            |
| <b>Transboundary issues</b>       | Great Lakes water quality degradation, unless limited to restricted bays or similar settings, typically has transboundary implications; hence, the development of the agreement in the first place. The agreement fostered the creation of additional transboundary governance initiatives in the area, such as the Cities Initiative (see 'Possible improvements').                                                                                                                                                                                                                                                                                   | Jetoo (2017)                                               |
| <b>Possible improvements</b>      | In 2003, the Great Lakes and St. Lawrence Cities Initiative (the Cities Initiative) formalized a network of over 130 cities that participate in measures for Great Lakes restoration and protection. The Cities Initiative relies on government funding, associate fees and private foundation funding. Therefore, access to supranational funding would be an improvement. IJC may also pay more attention to indicators of progress, so that all those engaged in protecting and restoring the resource are up to date on the progress achieved.                                                                                                     | Jetoo (2017)                                               |

The degree to which the 43 originally identified 'areas of concern' (AOC) have been addressed over time can indicate policy progress (**Figure 16.1**). The removal of 7 of the original AOC indicates a degree of success, although the 36 remaining areas highlight the difficulty of such remedial actions. As biophysical change may take decades to achieve in an AOC, a more immediate measure of policy progress is the adoption and implementation of policies to protect the Great Lakes in the areas in which specific remediation measures are undertaken.

The governments of Canada and the United States of America report on progress achieved under the agreement every three years through the 'Progress Report of the Parties', as well as through other means. The enabling factors for cooperation include the appreciation of the vast range of ecosystem services provided by the Great Lakes to the two countries. Furthermore, the two countries share similar visions, expectations and reliance on the Great Lakes. Finally, compared to many other areas in the world, they have the capabilities to meet the substantial policy, institutional, technical, financial and personnel obligations inherent in carrying out the objectives of the agreement.

The costs of the extensive monitoring, analysis and remediation of Great Lakes water quality issues are substantial. For instance, the Great Lakes Restoration Initiative, launched in 2010 to accelerate efforts to protect and restore the Great Lakes, has provided funds for projects amounting to more than US\$2.3 billion for the future functioning of the initiative (US EPA 2017). The efforts to enhance habitat for the fisheries include the removal of hundreds of small dams and culverts that partially or fully impede fish movement for spawning (Kemp and O'Hanley 2010). While economically a relatively minor activity, dam and culvert removal have an important impact on the aquatic life of the lakes and contribute to recreational value to the lake-side population. On the other hand, the removal of dams and culverts allows for spawning of some of the most aggressive invasive species in the lake, a side effect of the policy that requires a scientific assessment. The optimization models used by Neeson *et al.* (2015) indicate that the most cost-effective way of managing the Great Lakes restoration is when dams and road crossings are removed across the whole basin. The basin-wide approach results in doubling the habitat of fish species at a cost of US\$70 million, whereas a less integrated approach of addressing only dams or only road

**Figure 16.1: Map showing location and status of all United States of America and Canadian Great Lakes Areas of Concern**

Source: Binational.net 2018.

crossings results in striking inefficiencies of 24 per cent and 88 per cent less habitat, respectively. These results provide a cost-effectiveness argument for the ecosystem-wide approach taken by the IJC.

### 16.2.2 Adaptive management of environmental flows in the water and energy sectors

Concerns arising in response to degradation of river ecosystems due to diversion and impoundment of water have led to the widespread recognition of the importance of environmental flows (Poff *et al.* 1997; Arthington *et al.* 2006; World Bank 2018). They are defined as the “quantity, timing and quality of water flows required to sustain freshwater and estuarine ecosystems and the human livelihoods and wellbeing that depend on these ecosystems” (International River Foundation 2007). As a ‘master variable’ for the sustainability of aquatic ecosystems, environmental flows can be incorporated into national-level legislation on water resources management as well as river basin planning (Poff *et al.* 1997; Speed *et al.* 2013). For example, the South African National Water Act (1998) requires water reserves to maintain river health as well as basic human needs. The environmental flow concept is particularly useful in considering the nexus between environmental development and human demands.

One way to influence and secure environmental flows is to adjust the timings and volumes of water released from dams in an adaptive manner. This approach attempts to influence the water and energy (i.e. hydropower) nexus, as well as the water-food nexus in cases where irrigation is required for agricultural production in water-scarce areas. Adaptive management utilizes experimental data derived from large-scale flow-release experiments designed to test hypotheses on physical and biological responses to streamflow in rivers, floodplains or estuaries (Konrad *et al.* 2011, p. 949). High flow release experiments are complex interventions and affect a range of factors beyond flow variability, and can result in more efficient attainment of a wide range of ecological, social and economic benefits (Olden *et al.* 2014, p. 179).

Adaptive management is considered to provide more flexibility than traditional management approaches because it has means available to account for and test uncertainties. Adaptive management focusing on environmental flows can simulate how the natural hydrological regime affects the sediment, water and habitat regimes downstream and can be modified over time as new information becomes available (Richter *et al.* 2006, p. 299). However, adaptive management is often constrained by complex institutional settings and lack of financing (Kingsford, Biggs and Pollard 2011; Allan and Watts 2017). In addition, environmental flow experiments have been constrained so far to large dams in the United States of America, Australia and South Africa, with little reporting from other regions such as South-East Asia, South America and parts of Europe where a significant number of dams exist or are being planned (Olden *et al.* 2014, p. 178). While adaptive management would enable procedural justice to be built into the process through instruments such as public participation, there are equity and ethical concerns because experiments differentiate groups within society (Huitema *et al.* 2009).

Large-scale flow experiments are not without contention and their success or failure is contested based on stakeholder

perspectives (Olden *et al.* 2014, p. 177). The complexity and uncertainty of using flow experiments to inform adaptive management require a process for reflexive learning and incremental understanding (Sabatier *et al.* 2005). Active sharing of knowledge and collection of a diverse range of evidence regarding learning could further support the effectiveness of using environmental flows in adaptive management (Allan and Watts 2017). This feature of the policy approach addresses how responses can be influenced within the DPSIR framework (Section 1.6).

The following case study on the Colorado River below the Glen Canyon Dam in the United States of America highlights an example of a long-term commitment to experimentation and informed adaptive management used for the benefit of a spatially large area beyond the immediate dam catchment and for national conservation areas.

#### **Case study: flow experiments and adaptive management of Glen Canyon Dam on the Colorado River, United States of America**

Constructed in 1963, the Glen Canyon Dam impounds 300 kilometres of the Colorado River just upstream of Grand Canyon National Park, creating Lake Powell. The Colorado River carries a heavy sediment load that is integral to the habitat and ecology of the system. The dam had the effect of regulating river flow so that moderate flows are more frequent with less variance between high and low flows (Melis 2011, p. 8). Adaptive management was introduced as the negative impacts on aquatic and terrestrial species from the modified flow were observed; impacts such as riparian habitat loss and fish species endangerment (Collier, Web and Andrews 1997). Dam operating strategies began to take environmental flows into account with the Record of Decision of 1996 by the Secretary of the Interior setting up a flow experiment. The scheduled release of water from the dam aimed to artificially recreate conditions similar to pre-dam seasonal flows. The flow experiment addressed the water-energy nexus to “find an alternative dam operating plan that would permit recovery and long-term sustainability of downstream resources while limiting hydropower capability and flexibility only to the extent necessary to achieve recovery and long-term sustainability” (United States Department of the Interior [US DOI] 1996, p. G-11).

**Table 16.3: Evaluation of the effectiveness of adaptive management of the Glen Canyon Dam**

| Criterion                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | References                                                                                                                                                                                                          |
|-----------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Success or failure</b>         | The first experiment is considered to have been successful, paving the way for further experiments. The 2016 Record of Decision is a concrete example of an outcome that demonstrates the incremental nature of increased understanding of environmental flows.                                                                                                                                                                                                                                                        | US DOI (1996, p. G-11)                                                                                                                                                                                              |
| <b>Independence of evaluation</b> | The experiments and adaptive management approach have been evaluated by the United States Department of the Interior and United States Geological Survey, as well as extensively in peer-reviewed scientific literature.                                                                                                                                                                                                                                                                                               | Collier, Webb and Andrews (1997, p. 83); Webb <i>et al.</i> (1999); Meretsky, Patten and Stevens (2000); Hazel <i>et al.</i> (2006); US DOI (2008); Korman, Kaplinski and Melis (2010); Melis (2011); US DOI (2016) |
| <b>Key actors</b>                 | The Bureau of Reclamation and the National Park Services lead on setting out the adaptive management plan. These bodies engage with 15 stakeholder groups including other government agencies, river commissions, energy users and native tribes. The USGS Grand Canyon Monitoring and Research Centre plays a particularly important role in providing technical advice to government agencies and facilitates information exchange between these actors as well as civil society organizations.                      | US DOI (2016)                                                                                                                                                                                                       |
| <b>Baseline</b>                   | The experiments were designed to mimic pre-dam conditions. Natural floods occur at a higher frequency and scale, during which the mean velocity of the river is estimated to be five times greater than base flows                                                                                                                                                                                                                                                                                                     | Melis (2011, p. 7)                                                                                                                                                                                                  |
| <b>Time frame</b>                 | Multiple experiments have occurred over the span of two decades and the <i>Glen Canyon Dam Long-term Experimental and Management Plan</i> (US DOI 2016) is designed to inform the next 20 years of dam operation.                                                                                                                                                                                                                                                                                                      | US DOI (2016)                                                                                                                                                                                                       |
| <b>Constraining factors</b>       | An extensive list of laws, regulations and treaties constrains the alternatives for operation of Glen Canyon Dam and consideration must be given to a range of factors relating to the environment, cultural resources, tribal consultation, power marketing, and water allocation and delivery.                                                                                                                                                                                                                       |                                                                                                                                                                                                                     |
| <b>Enabling factors</b>           | Multiple pieces of legislation work in tandem, in other words policy coherence, across different scales and sectors, has been ensured as the legislation has evolved.                                                                                                                                                                                                                                                                                                                                                  | e.g. United States Congress 1973; US DOI (1992); US DOI (2018)                                                                                                                                                      |
| <b>Cost-effectiveness</b>         | The adaptive management decision of the Record of Decision 2016 used a comparison of seven options of dam operation and flow levels to assess costs and impacts. This enabled the finding that the net present value of adaptive management interventions compares favourably with the net present value of no action (status quo).                                                                                                                                                                                    | US DOI (2016)                                                                                                                                                                                                       |
| <b>Equity</b>                     | Consultation with stakeholders in the form of public participation has sought to identify different ways that various stakeholders engage in processes. However, it has been pointed out that some native tribes have experienced challenges in expressing their cultural values, which do not fit the mould of scientific inquiry and assessments, highlighting some issues of capacity to engage in public participation processes, as well as the confrontation of scientific knowledge with traditional knowledge. | Austin and Drye (2011)                                                                                                                                                                                              |
| <b>Co-benefits</b>                | The experiments have informed a set of co-benefits or 'resources goals' from the project site to downstream areas, ranging from cultural resources to recreational experience. Effects on human health from the experiments are not considered to be substantial (either as a benefit or harm), although it has been suggested that negative effects to health through degradation of water quality would be one criterion for terminating the experiments.                                                            | Valdez <i>et al.</i> (2000); Melis (2011); US DOI (2016)                                                                                                                                                            |
| <b>Transboundary issues</b>       | The experiments are required to meet the allocation specified in the Water Treaty between the United States of America and Mexico, as well as in the Code of Federal Regulations Title XVIII-Grand Canyon Protection, Section 1801.                                                                                                                                                                                                                                                                                    |                                                                                                                                                                                                                     |
| <b>Possible improvements</b>      | There are critiques that dispute-resolution mechanisms need to be further strengthened within the adaptive management approach.                                                                                                                                                                                                                                                                                                                                                                                        | Camacho, Susskind and Schenk (2010)                                                                                                                                                                                 |

The first high flow experiment was conducted in 1996. This was considered to be the first large-scale international flow experiment (Collier, Webb and Andrews 1997, p. 83; Meretsky, Wegner and Stevens 2000, p. 583). Further experiments were conducted in 2004 and 2008 (Melis 2011, p. 9) and additionally in 2012, 2013, 2016 and 2017. The first 16 years of high flow experiments have provided the basis for the high-flow experiment protocol (US DOI 2011) that provides for adaptive management of the Glen Canyon Dam. The effects of these experiments are analysed as part of the Environmental Impact Statement and adaptive management plans required under the National Environmental Policy Act. **Table 16.3** presents our evaluation of the effectiveness of adaptive management of the Glen Canyon Dam.

Through these experiments, scientific understanding and the policy approach for adaptive management have been incrementally modified to balance hydropower generation with ecological concerns (Gunderson 2015). The high flow release protocol has been successful in increasing the size of sand bars, with benefits to the endangered humpback chub, re-establishing of riparian vegetation and increasing recreation. The programme was successful in accomplishing these improvements within the bounds of existing agreements for water allocation and supply and integrating water management with hydroelectric demand.

Adaptive management was enabled through several policy elements. The mandate of the Bureau of Reclamation, an agency within the Department of Interior, is charged with balancing environmental and economic consideration when developing a dam (US DOI 2016). In addition, legislation such as the Endangered Species Act enables conservation of endangered species and the Grand Canyon Protection Act of 1992 recommends adaptive management (Meretsky, Wegner and Stevens 2000, p. 580). In addition, water supply to downstream states in the United States of America needs to be considered, not to mention in Mexico, as determined by the Water Treaty of 1944 between the two countries. Adaptive management therefore does not operate in an institutional void and multiple institutions cut across different scales, causing interdependence. Consequently, adaptive management requires comprehensive understanding of the set of institutions that can affect this policy approach.

The use of data as well as knowledge generation are also important where uncertainty is inherent in the flow experiments (Konrad *et al.* 2011, p. 955). In this regard, the United States Geological Survey (USGS) Grand Canyon Monitoring and Research Centre acts as a knowledge hub to facilitate experimentation and learning. Such uncertainty is both an enabling and constraining factor to making environmental flows and adaptive management approaches effective. Continuing experimentation and monitoring are vital in helping to modify strategies (Melis 2011, pp. 141-142).

### 16.2.3 A new approach to water-related disaster risk reduction

Disaster risk reduction is the “concept and practice of reducing disaster risks through systematic efforts to analyse and reduce the causal factors of disasters” (United Nations Office for Disaster Reduction [UNISDR] 2017). Disaster risk reduction aims to reduce the severity of a disaster, considering that the

occurrence of a natural hazard itself does not inevitably result in a disaster. Disaster risk reduction is therefore a preventative policy approach which includes objectives such as limiting exposure to hazards; reducing communities’ vulnerability to property loss and damage, displacement, mortality and other negative outcomes of disasters. Benefits include: better managing and monitoring of land, environment and resources; and improving preparedness, for example through early warning systems and evacuation plans (UNISDR 2017). The key point of disaster risk reduction is that, through appropriate policy choices and implementing such preventative actions, countries and States can reduce the scale of environmental disasters. Disaster risk reduction frameworks have evolved to provide more effort to preventively limit the size of the disasters, consider the extended time frames (currently 2015-2030, aligned to other global frameworks), and to place the emphasis on implementation, rather than on final aims (Inter-Agency Regional Analysts Network [IARAN] 2016, p. 4).

The impacts of disasters are unique to each region and they impact disaster risk governance arrangements. Often this leads to high investments in infrastructure, often accompanied by strongly institutionalized arrangements (e.g. Poland, Netherlands, Singapore). Yet moderate (Belgium, France) or highly (United Kingdom of Great Britain and Northern Ireland) diversified strategies emerge from both the need and will to change, and from a mix of forces pushing for this change (Wiering *et al.* 2017, pp. 20-24).

Improvements in national disaster risk reduction efforts and individual preparedness often emerge after major disaster events such as the 2004 Indian Ocean tsunami (Hoffmann and Muttarak 2017, p. 32). Disaster risk reduction is gaining a higher profile on political agendas through developments such as the targets of the Sendai Framework of Action (UNISDR 2015). At the same time, a person-centred approach is being promoted through greater engagement of women, children and older people. There are stark differences on the level of disaster preparedness between the developed and developing world, and this raises serious equity concerns in terms of the capacity to deal with disasters, and the subsequent loss of lives in the developing world (Al-Nammari and Alzaghal 2015).

Policies may address disaster risk reduction by improving their effectiveness, that, for example, may affect availability of potable water, depending on local/regional vulnerability and levels of preparedness. In particular, floods and storms represent direct pressures on water quality, while droughts affect both water quantity and quality. Effective policies can also enhance disaster risk reduction responses by addressing threats to the availability of safely managed drinking water and the affected sewerage systems which can have impacts on human health.

#### **Case study: Flood risk management policy in England and Wales (United Kingdom of Great Britain and Northern Ireland)**

Floods cause great financial losses and health impacts in England and Wales; the floods of 2007 caused £3.2 billion damage (Penning-Rowsell 2015). As of 2014, the number of households on floodplain areas as designated by the Environment Agency (only England and Wales) “constitute 8.5 per cent of all properties, with one quarter of these at significant risk” (Penning-Rowsell and Pardoe 2015, p. 5). As a result, flood risk management policy has seen major shifts in the last 15 years. Most notably, there is an emphasis

**Table 16.4: Evaluation of the effectiveness of the flood risk management policy in England**

| Criterion                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | References                                                          |
|-----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------|
| <b>Success or failure</b>         | The United Kingdom Government has claimed that the flood risk management system has been effective and "has achieved notable successes including securing better protection for more than 500,000 properties since 2005". There are, however, concerns about the equity implications of the new cost-benefit analysis based allocation of funds and the remaining preference for structural methods of flood risk management                                                                                                                                                                                                                      | United Kingdom Parliament (2017)                                    |
| <b>Independence of evaluation</b> | Sir Michael Pitt (2008) conducted an independent review following widespread flooding in summer 2007. The detailed assessment and recommendations of the review initiated a range of reforms in flood risk management as well as progress reports produced by DEFRA (2012). Chatterton <i>et al.</i> (2016) prepared an assessment of the costs and impacts of the 2013-2014 floods based on the categories of the 2007 assessment. The DEFRA report and the United Kingdom Government response in 2017 provide further material for assessing the policy.                                                                                        | Pitt (2008) ; DEFRA (2012); Chatterton <i>et al.</i> (2016)         |
| <b>Key actors</b>                 | The stakeholders include the United Kingdom Department of Environment, Food and Rural Affairs (DEFRA), the Environment Agency, local authorities, water companies, flood wardens, National Flood Forum, consultants. The main policy reform to-date consisted in giving the local authorities greater responsibilities for flood risk management.                                                                                                                                                                                                                                                                                                 | UK Government (2010); Laakso, Heiskanen and Matschoss (2016)        |
| <b>Baseline</b>                   | Adjusted for inflation, the average damages from floods in the United Kingdom of Great Britain and Northern Ireland in the last 23 years are approximately £250 million per year (Penning-Rowell 2015). Especially notable are the floods of the summer of 2007 with an estimated damage of £3.2 billion, which was a catalyst for the accelerated flood risk management reform.                                                                                                                                                                                                                                                                  | Penning-Rowell (2015)                                               |
| <b>Time frame</b>                 | The Floods and Water Act (2010) is based on an earlier strategy, 'Making Space for Water', introduced in 2004 (DEFRA 2004) and a more recent government strategy 'Future Water' (DEFRA 2008), as well as the influential report from Sir Michael Pitt (DEFRA 2008).                                                                                                                                                                                                                                                                                                                                                                               | DEFRA (2004); DEFRA (2008); Pitt (2008); UK Government (2010)       |
| <b>Constraining factors</b>       | The new policy framework has given local authorities the lead in preparing and responding to surface-water flooding without really equipping them with the necessary financial, human and technical capacity to deal with the new challenges. Local authorities across the country struggle with the high expectations for flood risk management as they remain underfunded and under-resourced.                                                                                                                                                                                                                                                  | Penning-Rowell (2015)                                               |
| <b>Enabling factors</b>           | The record funds allocated to flood risk management for hard, soft and natural solutions amounted to £2.5 billion in the period 2015-2021.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | Penning-Rowell (2015)                                               |
| <b>Cost-effectiveness</b>         | The fact that the devastating floods of winter 2013/14 have caused economic damage that is within the average annual damage in the last two decades (ca. £250 million) may indicate that the flood risk management measures passed since 2007 have been effective (Thorne 2014).                                                                                                                                                                                                                                                                                                                                                                  | Thorne (2014)                                                       |
| <b>Equity</b>                     | Some areas in the United Kingdom of Great Britain and Northern Ireland are more prone to flooding from surface water than others. The property insurance market is liberalized in the United Kingdom of Great Britain and Northern Ireland, which means that insurers may ask for higher premiums for houses located in areas under high risk of flooding. This puts some households at a disadvantage compared to others, raising concerns about the equity of flood risk management policy (Penning-Rowell and Pardoe 2015; Begg, Walker and Kuhlicke 2015).                                                                                    | Begg, Walker and Kuhlicke. (2015); Penning-Rowell and Pardoe (2015) |
| <b>Co-benefits</b>                | Natural flood management, based on land-use planning and change, can help mitigate non-point pollution from agricultural land, and reduce soil erosion impacts on lake ecosystems (Dadson <i>et al.</i> 2017), illustrating how system scale management can address a complex nexus dynamic. The restoration of terrestrial and aquatic habitats would provide additional carbon storage services (Keesstra <i>et al.</i> 2018). Potential co-benefits may include retention of water upstream in ponds and aquifers that can supplement scarce water resources during droughts, as well as help mitigate the adverse ecological impacts of heat. | Dadson <i>et al.</i> (2017); Keesstra <i>et al.</i> (2018)          |
| <b>Transboundary issues</b>       | None                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                                                                     |
| <b>Possible improvements</b>      | A future reform towards a stricter regulatory framework for sustainable drainage would be an improvement.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | Begg, Walker and Kuhlicke (2015)                                    |

on the 'softer' measures of flood prevention, nature-based solutions, and citizen preparedness, as outlined in the strategy 'Making Space for Water' (United Kingdom, Department for Environment, Food and Rural Affairs [DEFRA] 2004; Mukhtarov 2009) and included in the Flood and Water Management Act (United Kingdom Parliament 2010). This is as opposed to a heavier reliance on infrastructure (e.g. Wiering *et al.* 2017).

Another governance approach to flood risk management uses stakeholder collaboration at multiple levels and implements integrated water resources management (IWRM) through cross-sector coordination and greater engagement of citizens (Mukhtarov 2009). Local authorities now have a number of responsibilities in planning for and responding to surface water (e.g. flood waters) as a result of devolution of responsibilities from the United Kingdom Department of Environment, Food and Rural Affairs (DEFRA) and the Environment Agency as well as the outcomes of policy reviews (Pitt 2008) and the above-mentioned Flood and Water Management Act.

Policy has also encouraged that disaster risk reduction strategies consider biodiversity, human health and water quality benefits. The Pitt Review (Pitt 2007; Pitt 2008) called for sustainable drainage systems to be installed in new buildings and urban land-use change to reduce run-off and improve water retention. Currently, voluntary measures address sustainable drainage. **Table 16.4** presents our evaluation of the effectiveness of the flood risk management policy in England.

The United Kingdom of Great Britain and Northern Ireland case of flood risk management is a comprehensive reform of flood policy including the overhaul of surface-water management in England and Wales. Time will tell whether the new system is more effective than the previous one. However, major positive outcomes are already clear in terms of the large number of properties with better protection against flood risk, 500,000 since 2005 (United Kingdom Parliament 2017).

The continued success of the new flood risk management policy and its focus on surface-water management seems to depend on the ability of the national and regional governments to coordinate alleviation schemes and natural flood risk management with the local authorities. While more research into the outcomes of local management in flood risk strategies is necessary for a better understanding of its impacts, it seems reasonable to state that successful devolution of these responsibilities should be accompanied by increasing the budgets and coordinating powers of local authorities, together with a greater supporting role for the national bodies, such as the Environment Agency and DEFRA. While each local authority is responsible for leading in preparing for and responding to flooding, they require the necessary financial, human and technical capacity to deal with the new challenges. Local authorities across the country struggle with the high expectations for flood risk management as they remain underfunded (Begg, Walker and Kuhlicke 2015; Penning-Roswell and Johnson 2015). Furthermore, the multiple actors and responsibilities involved in the policy create a further challenge for coordinated implementation (Begg, Walker and Kuhlicke 2015).

#### 16.2.4 Economic incentives and subsidies for free basic water services

The right to water includes considerations of sufficiency, safety, acceptability, physical accessibility and affordability for personal and domestic uses (UN General Assembly Resolution A/RES/64/292, see United Nations, General Assembly [UNGA] 2010). A growing number of countries are now formally recognizing this human right following the 2010 UN General Assembly Resolution A/RES/64/292. The 2014 Global Analysis and Assessment of Sanitation and Drinking-Water reported that 70 out of 94 countries recognized the right to water (World Health Organization [WHO] 2014, p. 14).

Constitutions and legislation recognizing the right to water must be supported by policy instruments that target financing and budgeting. These instruments are important because financing and budgetary considerations are regarded as an obstacle to realizing the right to water and sanitation (de Albuquerque and Roaf 2012). States have often faced cost recovery and transaction cost issues (Obani and Gupta 2016, p. 679). Subsidies are part of water pricing efforts which provide economic incentives to realize the right to water. Subsidies are often used to support affordability of water and sanitation services, which include mechanisms such as income supplements, cross-subsidies, increasing block tariffs, universal price with rebate and free basic water (de Albuquerque and Roaf 2012, p. 54, 83).

The development of the MDGs enabled the human rights approach and treating water as an economic good to coexist, though there are tensions (Obani and Gupta 2014). Water pricing, if efficient, includes all of the economic costs required to provide water (Grafton 2017, pp. 30-31) and underscores that the right to water does not necessarily call for free water provision (United Nations Office of the United Nations High Commissioner for Human Rights [OHCHR] 2010, pp. 11-12). Moreover, the right to water needs to be considered within the wider context of multiple water uses, for example for food security, particularly at the household level. In general, the human right to water and sanitation does not consider how, for example, agricultural water requirements and virtual water transfer through trade could affect rich and poor users differently (Obani and Gupta 2016, p. 685). The right to water is thus defined by local contexts. The implication of rolling out this right indirectly illustrates the nexus of water and food security and the potential inequalities arising from differences in local contexts.

Within the DPSIR framework (Section 1.6), this policy approach is mostly aimed at guaranteeing a basic condition for safe and clean drinking water. Pricing and subsidies often operate within a broader governance context, including creating minimum requirements for water quality as well as establishing organizations as regulators (de Albuquerque and Roaf 2012). South Africa's free basic water policy is an early example of the constitutional recognition of the right to water, providing insight into over two decades of policy experience (see **Table 16.6**). It also exemplifies the need for economic instruments, such as increasing block tariffs, to be used in a way that considers local hydrological and socioeconomic contexts (von Hirschhausen *et al.* 2017).

### Case study: Free Basic Water Policy, South Africa

The South African Government launched the Free Basic Water Policy (FBWP) in 2001. Its purpose was to address public health concerns of lack of access to safe water and sanitation, and to provide subsidized water services to the country's population. The policy targets the poor in particular, and allows for the provision of 6,000 litres (6 kilolitres) of safe water per household per month (Department of Water Affairs and Forestry [DWAF] 2002, p. 7). By extension, the policy aims to alleviate poverty through the provision of basic services (DWAF 2002, p. 1) in a country that had experienced historic inequalities within the population.

The FBWP requires that approaches to restrict water consumption ensure effective free provision of a basic level of water supply. Recognizing that municipalities are not homogeneous, the FBWP suggests that mixed service levels are offered according to the consumer's ability to pay. Services include hand pumps, communal taps, and regulated yard and roof tanks as well as house connections (DWAF 2002). In addition, several types of economic incentives have been put forward to meet the variety of consumers within a municipality (see Table 16.5). Table 16.6 presents our evaluation of the effectiveness of economic incentives in the Free Basic Water Policy in South Africa.

The FBWP is an important first step to implementing the human right to water and brings together a set of legislation and policy instruments to consolidate the importance of this right. Municipalities are required to use a tariff system

according to Section 74 of the Municipal Systems Act. This tariff system reflects the 'user pays' principle so that water consumption above a basic level is charged (DWAF 2003, p. 29). Metering is one way to measure or control the amount of water supplied without charge (DWAF 2002, p. 29). However, the figure of 6,000 litres/household/month has been controversial and it was recognized in 2007 by DWAF (2007, p. 5) that the amount of 25 litres per person per day might not be enough for many households and needs to be incrementally increased.

The economics of implementation are not negligible because there is high regional as well as socioeconomic variation across the country, with implications for equity. For rural water supply, the cost recovery is very low (WSP 2011). Urban water supply has achieved 96 per cent coverage, but maintaining assets has received low priority, risking deterioration in the future (WSP 2011) and with possible impacts on cost-effectiveness.

Efficient cost recovery by water service authorities (i.e. municipalities) also comes with issues of equity. Problems with cost recovery impinge on the levels of service provision. The free basic minimum has become the maximum amount for households in places like Durban (Loftus 2006). Cost recovery is necessary to provide benefits to extend coverage and address geographical unevenness of burden so that FBWP is not exclusive to those that already have infrastructure and thus benefit from the subsidy easily (Balfour *et al.* 2005, p. 16).

**Table 16.5: Three options for free basic water supply**

|                  | <b>Option 1<br/>Rising block tariffs</b>                                                                                                                                                                                             | <b>Option 2<br/>Targeted credits</b>                                                                                                                                                                             | <b>Option 3<br/>Service-level targeting</b>                                                                                                                                                                                                                 |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description      | Rising block tariff is applied to all residential consumers, with the first block typically set from 0 to 6 kilolitres with a zero tariff. No fixed monthly charge applicable to those using below poverty relief consumption limit. | Each consumer who is selected for poverty relief gets a credit on their water account which would typically be sufficient to cover the charge for the poverty relief amount (often 6 kilolitres per month) free. | Those service levels which provide a restricted flow, (below the poverty relief consumption level) are provided at no charge. Those with higher service levels pay the normal tariffs, except for poor consumers who historically have high service levels. |
| Targeting method | No targeting (first 6 kilolitres free to all households). However, targeted fixed monthly charge may be necessary for holiday areas.                                                                                                 | Requires a system for identifying those who require poverty relief. Typically, this is based on a benchmark poverty indicator (household income or household expenditure).                                       | Targeting takes place through selection of service level by the consumer (or authority in some cases).                                                                                                                                                      |
| Applicability    | Mainly larger urban municipalities. Not suited to situations where there is a high proportion of holiday homes unless it is supplemented with a targeted fixed monthly charge.                                                       | Can be used in large municipalities but more typical for middle to small sized, largely urban municipalities. Requires a billing system to be in place for all consumers.                                        | Best suited to municipalities which are largely rural in character.                                                                                                                                                                                         |

**Table 16.6: Evaluation of the effectiveness of economic incentives through the Free Basic Water Policy in South Africa**

| Criterion                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | References                                                                                                                                                                                                                                                |
|-----------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Success or failure</b>         | The Department of Water Affairs and Forestry (DWAF) reported that there was a good track record of implementation particularly in urban areas during the first 22 months of implementing the provision of free basic water. In 2007, DWAF further reported that over 75 per cent of the population was provided with free basic water and the majority of those (69 per cent) were poor households. However, this success is uneven between urban and rural areas as provision of water supply in remote, rural locations has continued to lag behind. Moreover, it has been reported that drinking water provision decreased by 8 per cent from 2012 to 2014.                     | DWAF (2002); Muller (2008, p. 79); Water and Sanitation Program [WSP] (2011a, p. 2); Department of Water and Sanitation [DWS] (2014, p. 7)                                                                                                                |
| <b>Independence of evaluation</b> | The Free Basic Water Policy (FBWP) has been evaluated internally through review by DWAF, the Water Research Commission and other related government agencies, and extensively in the peer-reviewed scientific and grey literature.                                                                                                                                                                                                                                                                                                                                                                                                                                                 | DWAF (2002); Mehta and Ntshona (2004); Balfour <i>et al.</i> (2005); Loftus (2006); DWAF (2007); Loftus (2007); Muller (2008); von Schnitzler (2008); Dugard (2008); WSP (2011a); Naidoo <i>et al.</i> (2012); DWS (2014); Statistics South Africa (2016) |
| <b>Key actors</b>                 | DWAF (now the Department of Water and Sanitation [DWS]) is the ministry responsible for overseeing the FBWP. Central government has the role of regulator in this decentralized process. Municipalities, water boards and private service providers are involved in local implementation.                                                                                                                                                                                                                                                                                                                                                                                          | WSP (2011a)                                                                                                                                                                                                                                               |
| <b>Baseline</b>                   | There was no recognition of a right to water prior to policy implementation. When FBWP was introduced in 2001, it was reported that out of 44.8 million people, "5 million (11 per cent) had no access to safe water supply and a further 6.5 million (15%) did not have a defined basic service level" (DWAF 2003, p. 1).                                                                                                                                                                                                                                                                                                                                                         | DWAF (2003, p. 1)                                                                                                                                                                                                                                         |
| <b>Time frame</b>                 | The policy developed out of a wider political process of post-apartheid democratization after 1994. In addition, the FBWP has also been implemented and monitored during the period 2000-2015 to achieve the MDG Target 7C.                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                                                                                                                                                                                                                                                           |
| <b>Constraining factors</b>       | Physical constraints of water availability in a dry region challenge the provision of water supply. The policy has not defined a 'poor' household, despite it targeting such water users.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | Muller (2008); Naidoo <i>et al.</i> (2012)                                                                                                                                                                                                                |
| <b>Enabling factors</b>           | This policy enacts Section 27 of the Constitution, which states the right to water and is governed by the 1997 Water Services Act and the 1998 National Water Act. In addition, regulatory frameworks such as the 2003 Strategic Framework for Water Services guide the implementation of FBWP and are complemented by national standards on service levels such as DWS (2017). A mix of economic instruments is supported by the policy to help address provision in a situation where water has been bound up in social inequalities from apartheid. This policy is also part of an effort towards decentralization, and thus can be seen as part of a broader governance shift. | Muller (2008); DWS (2017)                                                                                                                                                                                                                                 |
| <b>Cost-effectiveness</b>         | The average per capita water supply investment in South Africa is relatively high (urban water supply US\$385 per capita; rural water supply US\$278 per capita). The uneven nature of cost-effectiveness is exemplified by the fact that across municipalities, the viability of cross-subsidization depends on a number of factors, including the level of wealth of consumers, and type and ratio of users.                                                                                                                                                                                                                                                                     | DWAF (2007); WSP (2011)                                                                                                                                                                                                                                   |
| <b>Equity</b>                     | According to one study, the disease burden attributable to unsafe drinking water and sanitation in South Africa in 2000 was estimated at 13,434 deaths, among which children were disproportionately highly represented (Lewin <i>et al.</i> 2007). The policy is a first step towards addressing these health implications. However, the use of prepaid water meters for cost recovery of water services has brought about a problem where consumption in excess of the free basic minimum becomes costly for some. The use of households as a unit of provision gives little attention to those in informal settlements and backyard dwellings.                                  | Bond and Dugard (2008); McDonald (2008)                                                                                                                                                                                                                   |
| <b>Co-benefits</b>                | The FBWP was set up to have co-benefits in public health, welfare and gender equity. Mehta and Ntshona (2004, p. 19) reported some evidence in this regard. However, published results and data on this aspect are not available in the public domain.                                                                                                                                                                                                                                                                                                                                                                                                                             | DWAF (2002); Mehta and Ntshona 2004, p. 19                                                                                                                                                                                                                |
| <b>Trans-boundary issues</b>      | While South Africa has several transboundary river basins and aquifers, the policy pertains to national aims and implementation, which do not seem to have direct or explicit implications for the exercise of the human right to water in other riparian states.                                                                                                                                                                                                                                                                                                                                                                                                                  |                                                                                                                                                                                                                                                           |
| <b>Possible improvements</b>      | Since the introduction of FBWP, the Free Basic Sanitation Policy was established in 2009. Co-benefits of the latter's implementation to FBWP could be analysed in detail in the future. Cost-effectiveness could incorporate health costs and deal with the efficacy of the Free Basic Sanitation Policy. Policy coherence could be further enhanced by integrative approaches involving better institutional interplay. A more specific focus on the needs of informal settlements would improve equity.                                                                                                                                                                          |                                                                                                                                                                                                                                                           |

### 16.2.5 Voluntary sustainability reporting on water in the mining sector

Mining requires significant amounts of water and presents considerable short- and long-term risks to water resources (Spitz and Trudinger 2008) (see also Section 9.5.5). The potential impacts on existing users and values of water resources are a common concern for local communities faced with both large- and small-scale mining projects. Such concerns stem from experiences of mines that have caused (or continue to cause) pollution or other impacts on water resources (e.g. reductions in stream flows, declines in groundwater levels, river diversions, undesirable changes in quality). Governments, companies and communities have recognized the fundamental need for the mining industry to manage water resource-related risks effectively (e.g. Norgate and Lovel 2006; Rankin 2011).

The main protocol for sustainability reporting is the Global Reporting Initiative (GRI), which began in 1997 as a coalition of government, community and corporate stakeholders, and aimed to make sustainability reporting as commonplace and important as corporate reporting. The current GRI standard includes a wide range of indicators across social, economic, environmental and local-community health aspects, and was designed to be used not only by the mining sector, but by any company or organization. It addresses equity issues through providing guidance on reporting on management approaches affecting vulnerable groups, the means by which local stakeholders are identified and engaged with, and the means by which companies address risks to and impacts on local communities. Since the Johannesburg Earth Summit in 2002, the global mining industry, through the International Council of Mining and Metals, now requires their corporate members to publish annual sustainability reports.

#### **Case study: Australian mining industry's Water Accounting Framework**

Early research into the water data reported by mines found that data in sustainability reporting could be changed from year to year without explanation, that different mines interpreted terms such as 'consumed water' or 'recycled water' inconsistently, and that water quality issues were poorly addressed (Mudd 2008; Northey *et al.* 2016). This led the Minerals Council of Australia (MCA) to develop the Water Accounting Framework (MCA 2012), which allows a mine's water balance to be quantified and the specific Global Reporting Initiative indicators to be reported through sustainability reports. The Water Accounting Framework was a major step forward in providing a consistent reporting approach to water management for mines. The 49-member companies of the MCA represent 85 per cent of Australia's mining activity and more than 90 per cent of mineral exports (MCA 2017a).

Growing interest in corporate responsibility has been a strong enabling factor for sustainability reporting, with pressures from investors and shareholders in mining companies as well as local communities affected by mining. The main constraining factor for water risks in mining is the technical capacity of an individual company and its mines. For example, a mine may not be equipped with the necessary monitoring, technical (especially water-balance modelling) expertise and reporting systems to ensure accurate and timely sustainability

reporting. Efficient management of water use and associated costs requires monitoring in any case, meaning that it is beneficial for a mine to invest in such systems to help it reduce operational costs, ensure transparency and improve its reputation, as well as minimizing water-resource-related risks. In terms of cost-effectiveness, the value gained from conducting good sustainability reporting compared to taking no action can be significant, from positive investor sentiment, a social licence to operate from a local community, reduction in operating costs from water efficiencies or recognition from regulators of successful environmental management – as noted by the MCA in its business case for the Water Accounting Framework (see MCA 2017b). **Table 16.7** below presents our evaluation of the effectiveness of the Australian mining industry's Water Accounting Framework.

The growing number of companies having adopted sustainability reporting is a sign of a successful policy initiative and approach. The fact that the MCA and now the International Council of Mining and Metals have mandated water reporting by their members also demonstrates success. However, four major weaknesses in the Water Accounting Framework and International Council of Mining and Metals protocols are:

- i. the issue of water quality of the water sources used in mining;
- ii. the links between detailed monitoring of potentially affected water resources, especially water quality and flows, and Global Reporting Initiative metrics;
- iii. links between regulatory requirements for water resources and sustainability reporting; and
- iv. improving the catchment and climate context of water data so that mining's use of water and risks to water resources can be more readily interpreted and understood.

Furthermore, there are very few formal evaluations of water data and information published in sustainability reports, except for a limited number of academic studies. With the Global Reporting Initiative moving to a standards framework rather than a guideline structure, independent auditing and assurance are now more prominent, as well as being important for responsible investors, regulators and interested community stakeholders.

The effectiveness of the policy in terms of the impact of mining operations on water resources generally has not yet been rigorously evaluated. However, the large proportion of Australian mining companies publishing sustainability reports incorporating the Water Accounting Framework suggests that the approach is useful as a management tool.

### 16.3 Indicators (link to SDGs and MEAs)

The following indicators on access to drinking water, sanitation and water withdrawal further examine the variety of policies used in managing freshwater resources, contributing to improving human health through various pathways. These indicators were selected for being policy sensitive and for being widely recognized for their importance under the current SDG targets and established multilateral environmental agreements. For the purposes of this chapter, the indicators are analysed in order to present policies influencing global

**Table 16.7: Evaluation of the effectiveness of the Australian mining industry's Water Accounting Framework**

| Criterion                         | Description                                                                                                                                                                                                                                                                                                                                        | Reference(s)                                                              |
|-----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------|
| <b>Success or failure</b>         | The growing number of companies that have now adopted sustainability reporting in Australia, as well as the fact that both the Minerals Council of Australia (MCA) and International Council of Mining and Metals (ICMM) have mandated water reporting, signals successful diffusion of the policy approach.                                       | Mudd (2008); Northey, Haque and Mudd (2013)                               |
| <b>Independence of evaluation</b> | With the Global Reporting Initiative (GRI) moving to a standards framework rather than a guideline structure, external assurance auditing is being increasingly conducted, although the extent of such auditing is variable. Very few formal evaluations of water data reporting have been done.                                                   | Mudd (2008); Northey <i>et al.</i> (2016)                                 |
| <b>Key actors</b>                 | Individual mining companies, their membership associations, local communities, interested stakeholders (e.g. environmental groups), government regulators, financial stakeholders.                                                                                                                                                                 | Franks <i>et al.</i> (2014)                                               |
| <b>Baseline</b>                   | There was no formal baseline. A tacit baseline could be the lack of water reporting prior to the mid-1990s.                                                                                                                                                                                                                                        | Mudd (2008)                                                               |
| <b>Time frame</b>                 | The process of sustainability reporting and the data it contains have evolved over the past 20 years. From 2016, the GRI has been a formal standard rather than a guideline.                                                                                                                                                                       | Mudd (2008); Northey, Haque and Mudd (2013); Northey <i>et al.</i> (2016) |
| <b>Constraining factors</b>       | Companies and mines are constrained by their technical capacity to monitor and record water-related processes and impacts.                                                                                                                                                                                                                         | Mudd (2008); Northey, Haque and Mudd (2013); Northey <i>et al.</i> (2016) |
| <b>Enabling factors</b>           | The growing interest in demonstrating corporate responsibility, with pressures from investors and shareholders in mining companies as well as communities affected by mining.                                                                                                                                                                      | Mudd (2008); Franks <i>et al.</i> (2014); MCA (2017a)                     |
| <b>Cost-effectiveness</b>         | It is logical for companies to engage in self-reporting to avoid project-delaying conflicts, expensive litigation and brand damage. Also, good sustainability reporting may lend companies a social licence to operate from local communities.                                                                                                     | Mudd (2008); Franks <i>et al.</i> (2014);                                 |
| <b>Equity</b>                     | Although sustainability reporting may result in win-win situations for mining companies, communities and government in Australia, it is unclear how sustainability reporting might impact on equity in other parts of the world.                                                                                                                   | Franks <i>et al.</i> (2014)                                               |
| <b>Co-benefits</b>                | Sustainability reporting results in data availability to researchers, enabling quantification of the life cycle costs of specific metals and minerals, innovation that may benefit the sustainability of processes, and evaluation of impacts of new mining technologies on water resources.                                                       | MCA (2017a)                                                               |
| <b>Transboundary issues</b>       | The global uptake of standardized sustainability reporting may foster improved transnational management of mining water-related issues.                                                                                                                                                                                                            | International Council of Mining and Metals (ICMM) (2017)                  |
| <b>Possible improvements</b>      | Detailed study of water-resource-related sustainability reporting by companies should be conducted to assess its extent, quality and effectiveness. There are major weaknesses in the Water Accounting Framework and ICMM protocols. Online databases of pooled water-resource data would foster usability of water data and improve transparency. | Mudd (2008); Northey, Haque and Mudd (2013); Northey <i>et al.</i> (2016) |

trends in drinking water and sanitation and water withdrawal. There is a considerable diversity of policies and our analysis underscores the importance of policy mixes in further achieving global targets such as the SDGs and facilitating implementation at the local level.

### 16.3.1 Indicator 1: Proportion of population using safely managed drinking water services

SDG indicator 6.1.1 is defined as the proportion of the population worldwide using safely managed drinking water services, in support of public health. 'Safely managed' refers to water from an improved water source located on

premises, available when needed and free of faecal and priority chemical contamination (WHO and the United Nations Children's Fund [UNICEF] 2017), wherein 'improved water source' (the MDG indicator) includes rainwater, water that is piped, made available from taps, standpipes, boreholes, wells or springs, or is packaged or delivered. 'Drinking water services' refers to the accessibility, availability and quality of the main source used by households for drinking, cooking, personal hygiene and other domestic uses (WHO and UNICEF 2017). Priority chemical contaminants vary by country, but arsenic and fluoride are assigned as priority contaminants globally due to their potential impacts on human health.

## Scope and measurement

From 2000 to 2015, the World Health Organization and United Nations Children's Fund (WHO/UNICEF) Joint Monitoring Programme for Water Supply and Sanitation (JMP) used a binary classification of improved/unimproved sources of drinking water as an indicator for monitoring and evaluation purposes. In order to monitor SDG target 6.1, the JMP further developed this indicator to facilitate further differentiation between service levels and assessment of safe management of supplies (WHO and UNICEF 2017). Corresponding updates were made to the JMP drinking water service ladders with 'safely managed' occupying a new rung positioned at the top (Table 16.8).

According to the JMP, 2.6 billion people worldwide gained access to an improved source of drinking water in the period between 1990 and 2015 (UNICEF and WHO 2015) (Figure 16.2). This brought the proportion of the global population using piped water supplies on premises to approximately 75 per cent.

## Policy relevance

This indicator is a modification of the MDG indicator 7.8 (proportion of population using an improved drinking water source) and directly relates to SDG target 6.1, which aims to achieve universal and equitable access to safe and affordable drinking water for all by 2030. This indicator also relates to long-standing global policy efforts addressing water and human health, including multilateral environmental agreements such as the 1999 Protocol on Water and Health.

## Causal relations

The gradual shift towards water governance can be broadly attributed to changes in the provision of safe drinking water services. The initial intervention involves installing physical infrastructure for safe water supply. For example, efforts that upgrade water services to piped supplies typically reduce microbial contamination of both source and household-stored water quality (Shields *et al.* 2015). While technical solutions are still seen in the sanitation sector (WSP 2011b), there is increasing use of participatory approaches to complement them (see also Section 16.2.2). In India, for example, the national water policy aiming to provide safe water adopts a socio-technological approach (Khurana and Sen 2008).

Target setting at the national level also appears to encourage an increase in the size of populations with access to safe drinking water. In a recent assessment of water access in 97 countries, approximately half had established or were working towards universal access as a target between 1980 and 2013 (Luh *et al.* 2017). The MDG on safe drinking water halved the proportion of people requiring access by 2012, three years before the MDG deadline. This early success has been followed up with national targets motivated by the ambitious global goals of the SDGs: countries with the appropriate capacity can be expected to meet ambitious targets, leading to greater coverage than is found in countries lacking such ambitious targets (Luh *et al.* 2017).

## Other influencing factors

Universal access may be hampered not only by hydrological factors such as rainfall, which may contribute to water scarcity, and water-related hazards such as microbial contamination, but also by economic factors. In rapidly developing countries such as India, pollution and overexploitation of water are linked to industrialization and agricultural expansion, which in turn influence water quality (Khurana and Sen 2008). The pace of population growth also challenges drinking water and sanitation coverage, especially in sub-Saharan Africa and Oceania (UNICEF and WHO 2015).

A lack of awareness or understanding of water quality problems may hinder safety of drinking water services in both developed and developing countries. In Bangladesh, while tube wells have increased, water quality testing is not commonly practised (Fischer 2017). This contributes to poor understanding of the health risks posed by both microbial and non-microbial contaminants. This can have serious consequences in terms of public health. For example, measures taken in the 1970s to reduce the health impacts of microbial disease from surface-water use resulted in the widespread installation of tube wells, themselves a source of water with high levels of inorganic arsenic (Flanagan, Johnston and Zheng 2012). Populations using these sources for drinking water have experienced severe health consequences ranging from skin lesions to cancer and cognitive effects (Abdul *et al.* 2015), resulting in stigmatization and other serious social impacts (Kabir *et al.* 2015).

## Possible alternative indicators

A useful alternative indicator to understand the population benefiting from safely managed drinking water services might focus on disparities between rural and urban populations combined with wealth quintiles. The JMP has been able to track coverage between 1995 and 2012 (UNICEF and WHO 2015) but could benefit from comprehensive data and rigorous reporting.

**Table 16.8: The JMP Service Ladder for drinking water**

| Service level                                                                                             | Definition                                                                                                                                              |
|-----------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Safely managed</b>  | Drinking water from an improved water source which is located on premises, available when needed and free of faecal and priority chemical contamination |
| <b>Basic</b>           | Drinking water from an improved water source provided collection time is not more than 30 minutes for a roundtrip including queuing                     |
| <b>Limited</b>         | Drinking water from an improved source where collection time exceeds over 30 minutes for a roundtrip to collect water including queuing                 |
| <b>Unimproved</b>      | Drinking water from an unprotected dug well or unprotected spring                                                                                       |
| <b>No service</b>      | Drinking water collected directly from a river, dam, lake, pond, stream, canal or irrigation channel                                                    |

Figure 16.2: Change in global population by drinking water source, 1990-2015 (billions)

Source: Adapted from WHO and UNICEF (2017).

### 16.3.2 Indicator 2: Proportion of population using safely managed sanitation services, including a hand-washing facility with soap and water

SDG indicator 6.2.1 refers to the proportion of the population using safely managed sanitation services, including a hand-washing facility with soap and water, wherein 'safely managed' is defined as "an improved sanitation facility which is not shared with other households and where: excreta is safely disposed of *in situ*, or excreta is transported and treated off-site" (WHO 2017, p. 1).

#### Scope and measurement

The levels of sanitation services vary from safely managed, through basic, limited and unimproved, to no service according to the JMP. These levels focus on whether excreta is separated and disposed of safely, avoiding human contact. In addition, the levels depend on whether sanitation facilities are shared or private (WHO 2017).

#### Graphical representation

There has been great progress made in decreasing the number of people without access to safe sanitation services. As **Figure 16.3** shows, between 2000 and 2015 the number of people practising open defecation declined from 1,229 million to 892 million, which is an average reduction of 22 million people per year. Furthermore, all regions have made progress in decreasing this indicator apart from sub-Saharan Africa and Oceania.

Figure 16.3: Regional trends in proportion of national population practising open defecation, 2000-2015

Source: WHO and UNICEF (2017).

Another notable trend is the rate of change in various countries in the world. While 14 countries have shown progress sufficient to be on track for universal basic sanitation by 2030, the majority either need to accelerate progress or to reverse a negative trend of increasing number of people with no access to safe sanitation (Figure 16.4).

### Policy relevance

The proportion of the population using safely managed sanitation services directly relates to the SDG target 6.2: "by 2030, achieve access to adequate and equitable sanitation and hygiene for all, and end open defecation, paying special attention to the needs of women and girls and those in vulnerable situations" (United Nations 2018). SDG indicator 6.2.1 increases recognition of these relationships and furthers ongoing global efforts to address water and sanitation, including the MDGs preceding this SDG target, as well as the Plan of Implementation of the World Summit on Sustainable Development.

### Causal relations

Improved water supply and sanitation are the most fundamental indicators related to water, sanitation and hygiene (WASH) interventions. Policy interventions have aimed to provide and maintain infrastructure such as wells, water transport and distribution networks, and water-treatment facilities (Hunt 2011). Water quality interventions and hygiene promotion such as handwashing have also been effective in prevention of disease (Peletz *et al.* 2013).

Community-led total sanitation (CLTS) has been actively taken up in many parts of the world to improve the number of people using improved sanitation services. CLTS is the main policy used to tackle open defecation in rural areas in developing countries (Bateman and Engel 2017). The uptake has been rapid with 60 countries implementing CLTS since 2000 (Crocker *et al.* 2017). CLTS is a participatory and bottom-up approach that incorporates awareness-raising at the community level.

One reason for the spread of CLTS is its perceived low cost, even given the relative scarcity of studies examining its true costs (Crocker *et al.* 2017).

### Other influencing factors

As with access to safe drinking water services, sanitation is a focus of global ambitions as reflected in the SDGs. However, rather than attempting to assess WASH and preventative health interventions at the global level, it is more effective to decentralize policy so as to better understand those factors that serve to enable WASH in local contexts (Whittington *et al.* 2012).

### Possible alternative indicators

The concomitant rise in pit-latrine sanitation and groundwater use has led to increasing concerns about the potential impact of resulting contamination of drinking water on health. In order to measure the robustness of sanitation service hygienically separating excreta from human contact, consideration may be required to not simply measure the sanitation service provision but also any secondary or knock-on effects. Indicators based on integrated data to identify and mitigate risk could be useful and it has been suggested that water supply and pit-latrine mapping is effective, as well as the monitoring of key groundwater contamination indicators (Back *et al.* 2018).

### 16.3.3 Indicator 3: Level of water stress: freshwater withdrawal as a proportion of available freshwater resources

SDG indicator 6.4.2 refers to level of water stress (freshwater withdrawal as a proportion of available freshwater resources). Water withdrawal can be defined as the amount of freshwater resources removed from rivers or aquifers for agricultural, industrial and domestic uses (Food and Agriculture Organization of the United Nations [FAO] 2016). Agricultural water use makes up the majority of global water withdrawal, underscoring a major dimension of the water-food nexus

**Figure 16.4: Progress towards universal basic sanitation services (2000–2015) among countries where at least 5 per cent of the population did not have basic services in 2015**

Source: WHO and UNICEF (2017).

(see Sections 4.4.3 and 9.8.2) with consequences for livelihoods, nutrition, public health and well-being. Agricultural water withdrawal is used for irrigation, livestock and aquaculture (FAO 2016). In particular, irrigation makes up the majority of total water withdrawal (67 per cent) (United Nations World Water Assessment Programme [WWAP] 2016).

### Scope and measurement

Water withdrawal trends indicate how human use of fresh water has changed over time. At the global level, over the last century water withdrawal has increased (Figure 16.5). The changes to blue water withdrawal suggest how irrigation has increased over time. The ratio of agricultural water withdrawal to total water withdrawal within a country varies across the globe with factors such as climate and priority given to agricultural activity (Figure 16.6). The development of dams has contributed to anthropogenic water use and evaporation from storage of water in lakes or reservoirs. However, this type of water withdrawal is not currently reflected in the indicator discussed in this section (FAO 2016).

Source: Adapted from FAO (2015).

**Figure 16.7: Changes in global gross crop water demand over time**

Source: Wada, van Beek and Bierkens (2012, p. 14)

#### Policy relevance

This indicator is directly relevant to SDG target 6.4: By 2030, substantially increase water-use efficiency across all sectors and ensure sustainable withdrawals and supply of fresh water to address water scarcity and substantially reduce the number of people suffering from water scarcity. Concerns over water quantity have been repeatedly raised in global policies and numerous multinational environmental agreements such as the 1977 Mar del Plata Action Plan, 1992 Dublin Statement of Water and Sustainable Development, the 1997 Convention on the Law of the Non-navigational Uses of International Watercourses (United Nations Watercourses Convention), the 1992 Convention on the Protection and Use of Transboundary Watercourses and International Lakes (UNECE Water Convention), and the International Law Commission's 2008 Draft Articles on the Law of Transboundary Aquifers. In addition, this indicator also draws attention to the balance between water for agriculture and water for industrial, household and ecosystem needs,

which is addressed specifically in SDG target 6.5 advocating integrated water resources management (IWRM).

#### Causal relations

Subsidies are a major contributor to the expansion of irrigation agriculture. Full cost recovery rarely happens in developed countries. In developing countries, water user associations have been set up to decrease use of subsidies and charge for water use. However, such charges are not sufficient to meet full cost recovery (Toan 2016). Consequently, the price of irrigation undermines supply cost and disregards impacts on the environment. It has been suggested that the 'polluter pays' principle should be included in the price of irrigation (Howarth 2009).

While large-scale public investment in irrigation has been made in the past, it is unlikely for investments at such scale to be made in future. Instead, participatory irrigation management and irrigation management transfer are providing investment at the local scale and proving very popular (Turral *et al.* 2010).

Groundwater is increasingly used for agricultural purposes (Figure 16.7). In particular, private groundwater wells and abstraction have become the main method for irrigation in India and are used widely in other developing countries such as China, Pakistan and Thailand (Turral *et al.* 2010). Here, the water-energy nexus is evident as cheaper pumping technology and easier energy access has enabled extraction, often at the individual level (Shah 2014). However, groundwater governance, especially for transboundary aquifers, has yet to be well established (Albrecht *et al.* 2017). There are also reported cases where efforts to improve irrigation efficiency have not contributed to the reduction of groundwater use, but rather the opposite (Pfeiffer and Lin 2014).

#### Other influencing factors

Molden *et al.* (2010) suggest supply management focusing on allocation has had a bigger impact on water efficiency than pricing to influence the behaviour of farmers. However, in large river systems, supply management through dams can lead to increased irrigation activity whereby dam-impacted catchments have 25 times more economic activity per unit of water compared with non-impacted catchments (Nilsson *et al.* 2005).

#### Possible alternative indicators

Vörösmarty *et al.* (2010) examined the ways human water security and biodiversity threats intersect globally. An indicator of these composite factors shows effects not only water withdrawals but also downstream and on ecosystems, beyond meeting water needs for agricultural output. Alternative indicators could provide insight into water scarcity at the subnational level. Considering that water scarcity is experienced at local level, alternative indicators could cover the spatial variation of water scarcity within countries. There are some emerging concepts and methodologies, for example the World Resources Institute Aqueduct water risk mapping makes detailed data accessible to a range of users including investors and companies (<https://www.wri.org/our-work/project/aqueduct>).

## 16.4 Discussion and conclusions

Various policy approaches show that water quantity and quality have serious implications for human and ecosystem health, and that these interactions are driven by changes in multiple sectors. Governance is increasingly opened up to non-State actors, such as the private sector and civil society. Decision-making thus needs to consider the full range of sectors and actors so that drivers and pressures (see Chapters 2 and 9) are addressed in an integrated fashion, considering economic, social and environmental issues. Achieving policy coherence and synergy are important features of the nexus interactions between fresh water and other sectors. Policy interventions should be designed to exceed purely technical fixes. This does not diminish the importance of provision of infrastructure such as wells, latrines and dams, but such provision should be considered within the complexity of a policy mix and with coherence in mind. In several case studies, public participation and stakeholder engagement have been implemented. However, the distribution of burdens and benefits of policies could be improved to address issues of equity and environmental justice.

The governance approaches and policy types examined in this chapter were not assessed in terms of evaluating non-monetary values. Where economic evaluations were conducted, trade-offs were mainly captured in monetary terms, and typically failed to assess impacts on human health or ecosystems. Negative impacts of policies on health have typically focused on natural hazards or infectious disease, and little has been done to capitalize on the potential co-benefits on human health (Grellier *et al.* 2017) or ecosystems.

Effective policies may be sought through active involvement of stakeholders. However, devolution of water governance does not necessarily result in better stakeholder engagement, as illustrated in the disaster risk reduction policy in England and Wales (Section 16.2.3); capacity-building and long term efforts of awareness-raising and knowledge use are also required to enable effective stakeholder involvement.

Monitoring thresholds and baseline conditions are a key component in the implementation of policy as well as for ensuring its overall effectiveness. Baseline conditions should be defined at implementation and subsequently monitored, causal relationships should be hypothesized and tested, and counterfactual thinking used to avoid misattribution of policy effectiveness due to confounding factors (Ferraro 2009). This is particularly true of access to safe drinking water and sanitation.

The selection of case studies in this chapter was guided by a number of requirements, in particular that case studies are described in depth in peer-reviewed literature, and as such the cases were drawn chiefly from developed economies. Developed economies are often equipped with resources and structures that allow for experimentation and innovation; accordingly, lessons learned from developed world case studies are not intended to be applied globally. On the contrary, a cautious approach should be taken with problems considered on a case-by-case basis, when embedded in their own specific context (Ingram 2013; Mukhtarov *et al.* 2015).

## Executive summary

**The physical, social, economic and health impacts of climate change, especially on the most vulnerable communities, require urgent adaptation approaches that are systemic, multidimensional and transformative** (*established but incomplete*). Climate change adaptation is a complex process and needs to occur in all regions and sectors, at multiple temporal and geographical scales. It must consider the complex and interacting elements and feedback mechanisms of the human-environment system. {17.3.1}

**Climate adaptation in coastal cities and small island developing states (SIDS) is generally categorized as 'protect', 'accommodate', 'retreat'** (*established but incomplete*). Adaptation needs to deal with multiple slow and rapid onset hazards such as coastal erosion, sea level rise, tropical cyclones, floods or drought. Climate adaptation in coastal cities is still insufficient and may lead to increased risks in the future. Many low-lying SIDS are experiencing intensified flooding and coastal erosion and the area may become uninhabitable in the long term. {17.3.1}

**A transformative approach for climate adaptation needs to deal with uncertainties and complexities** arising from climate change impacts, address the drivers of risks and deal with the underlying factors of vulnerability, reduce inequality, address gender empowerment, and build resilience and adaptive capacity (*established but incomplete*). {17.3.3}

**The agrifood system is responsible for significant environmental externalities, including greenhouse gas emissions, and is highly inefficient on an energy basis** (*well established*). Achieving the Sustainable Development Goals (SDGs) requires urgent action to reduce the agrifood system's environmental footprint and increase its overall efficiency. {17.4.1}

**Agriculture is responsible for the majority of environmental consequences associated with food production** (*well established*). The two broad policy approaches for addressing this are: (1) incorporating the cost of negative environmental externalities into market prices via the 'polluter pays' principle; and (2) incentivizing farmers to minimize negative externalities or create positive externalities through payments for ecosystem services, which might be considered as the 'beneficiary pays' principle. {17.4.2}

**Without a change in global dietary trends, food system emissions growth may mean that the Paris Agreement goal of limiting warming to well below 2°C is unlikely to be reached** (*established but incomplete*). Most environmental policies in this area are oriented towards addressing the sustainability of food production, with less attention paid to waste and consumption. Several governments have introduced economic policy measures to encourage environmentally sensitive farming practices. There are nascent signs of sustainability criteria being incorporated into dietary guidelines to convince consumers to adjust their consumption patterns to optimize nutritional outcomes and to reduce the environmental burden of doing so. {17.4.3, 17.4.4}

**Long-term planetary sustainability requires policy and technological interventions across energy systems to bring about choice of fuels**, the way they are produced and consumed, and the way in which resources are affected systemically at every stage of the energy system (*established but incomplete*). {17.5.1, 17.5.2}

**Mechanisms to address these challenges** include carbon pricing (cap and trade systems, carbon taxes and other economic instruments such as fuel taxes and different subsidies to renewable energy), regulatory approaches (energy efficiency standards, command-and-control, mandatory decommissioning of old plants), information programmes (addressing behaviour, lifestyle and culture), and addressing administrative or political barriers (including through international cooperation) (*established but incomplete*). {17.5.3}

**Decarbonizing supply and improving demand efficiency are two key policy elements that have been applied successfully** (*well established*). Nevertheless, they need to be scaled up rapidly, together with the phasing in of new policies. {17.5.4}

**The global economy currently operates predominantly in a linear mode** whereby resources are extracted, converted through manufacturing to products and then disposed of (*well established*). {17.6.1}

**The use of natural resources has grown rapidly** over the last two decades and the global supply chains of resources have become more complex, resulting in growing environmental pressures and impacts (*well established*). {17.6.1}

**A global shift is needed to a circular economy in which resource efficiency contributes to economic growth and human well-being**, with reduced environmental pressures and impacts (*established but incomplete*). This would have substantial co-benefits for greenhouse gas abatement and waste and pollution minimization. {17.6.2}

**A circular economy is a systems approach to industrial processes and economic activity that enables resource to maintain their highest value for as long as possible** (*well established*). Key considerations in implementing a circular economy are reducing and rethinking resource use, and the pursuit of longevity, renewability, reusability, reparability, replaceability and upgradability for resources and products that are used.

**Resource efficiency contributes to economic resilience** by increasing the supply security of primary materials and closing of resource loops through remanufacturing and recycling, thereby reducing the pressures of resource exploitation, climate change, accumulation of toxic substances in ecosystems, and biodiversity loss (*well established*). {17.6.2}

**Resource efficiency does not always happen spontaneously but requires well-designed policies** that facilitate a change to sustainable systems of production and consumption and sustainable infrastructure (*established but incomplete*). {17.6.4}

**Systems, product and service design that reduce demand and increase efficiency in resource use are key to bringing about the circular economy** (*inconclusive*). Cross-sector and cross-disciplinary collaboration that empowers consumers as citizens is also key. {17.6.4}

**Resource efficiency, greenhouse gas abatement and waste minimization policies, implemented together, will enable the decoupling of economic development and human well-being** from global environmental degradation and resource exploitation (*inconclusive*). {17.6.4}

## 17.1 Cross-cutting policy issues and systemic change

The 2030 Agenda for Sustainable Development affirms the determination of governments to “take the bold and transformative steps which are urgently needed to shift the world on to a sustainable and resilient path.” Achieving this transformation requires urgent and dramatic change in cross-cutting sustainable development policy areas which have closely intertwined social, economic and environmental dimensions.

Chapter 4 of this report identifies 12 cross-cutting issues of immediate concern for policymakers: health, environmental disasters, gender, education, urbanization, climate change, polar regions and mountains, chemicals, waste and wastewater, resource use, energy, and the food system. Because of their link to key economic, social and environmental systems, four of these 12 cross-cutting issues – climate change, food, energy and resource use – are selected for further analysis here.

This chapter evaluates the capacity of environmental policies to achieve transformational change in addressing cross-cutting global sustainable development challenges. To this end, the chapter addresses the major challenges of adapting socioeconomic systems to climate change, creating a sustainable agricultural and food production system, decarbonizing energy systems, and creating a circular economy. The world's pressing environmental challenges are the consequence of deeply rooted socioeconomic systems that reach across multiple policy areas. If global human needs are to be met within planetary boundaries there must be a transformation in the operation of these systems to reduce biophysical resource use and achieve just social outcomes (Raworth 2012; O'Neill *et al.* 2018). Systemic transformation will be very challenging for some communities but will provide a range of benefits and opportunities. Some of these opportunities can be realized in the short term, others over a longer period. In order to achieve a transformation which attracts widespread support, the opportunities and challenges will need clear communication, the expectations of affected groups and sectors will need to be considered, while those who suffer dislocation or negative distributional impacts from change will need to be compensated, retooled and reskilled.

### 17.1.1 A safe operating space

Transforming global systems towards a sustainable and resilient path is a major challenge because of the legacy of past policies, knowledge systems and cultural norms (Economic and Social Commission for Asia and the Pacific [ESCAP], Asian Development Bank [ADB] and United Nations Development Programme [UNDP] 2018) and because of the inherent complexity in policy arenas, involving many issue areas and actors. Climate change, for instance, has been described as a “diabolical policy problem” because its solution requires high levels of cooperation among governments and the implementation of policy measures across many economic sectors (Garnaut 2008).

In the Anthropocene, cross-cutting policy challenges involve a tightly coupled interdependency between the biophysical and socioeconomic elements of the Earth system (Liu *et al.*

2007; Biermann 2014; Young 2017). The central challenge for environmental policy in this new era is meeting human needs in a way that does not overstep planetary boundaries, and stay within a safe operating space for humanity (Rockström *et al.* 2009). For this objective to be reached there must be a radical reduction in biophysical resource use and a transformation in physical and social provisioning systems which connect resource use to just social processes and outcomes (Raworth 2012; O'Neill *et al.* 2018).

In pursuing transformation, it is vital that policymaking is strategic, coordinated and directed to the achievement of a clear vision. Environmental policies that address only one aspect of a systemic, cross-cutting, sustainable development challenge are unlikely to achieve the change necessary to shift the earth's socio-ecological systems to a pathway towards sustainability. For example, an isolated policy for reducing greenhouse gas emissions for one product may provide an economic incentive for production to shift to another, unregulated, product with the result that there is no net or economy-wide emissions reduction (Yang *et al.* 2012; van den Bergh *et al.* 2015). This is why in some contexts general regulation is preferable to technology-specific policies that ‘pick winners’. Cross-cutting environmental issues must therefore be approached holistically, with policy interventions implemented with the objective of transforming the relevant system as a whole, including shifting collective behaviour and changing unsustainable social practices and norms.

However, setting the necessary and ambitious goal of transforming socio-economic or socio-technical systems does not always mean that the environmental policies directed to achieve this goal must be all-encompassing. An effective strategy for transformation that pursues a clear and overarching vision can be given operational effect through environmental policies applicable at macro, medium and micro scales. In some policy contexts, small-scale targeted interventions that can create innovation will be more effective than expansive policies. From this perspective, promotion of specific technological or social innovation can in some circumstances be justified. There is evidence that transformation of some socio-ecological systems can begin from change made within niches that can lead to technical and other innovations that result in more sustainable patterns of resource use (Doyon 2018). While small changes to one system may lead rapidly to a tipping point and a transformation of the system, other systems are more entrenched and robust and not easily shifted to a sustainable mode. Breaking through this path dependency requires a suite of policies and approaches at multiple scales.

## 17.2 Key actors, policies and governance approaches

Globalization has resulted in the emergence of complex global socio-ecological systems that do not operate in a predictable way and can give rise to nonlinear change. This means that policymaking and implementation occurs under conditions of uncertainty and there is an increasing premium on environmental governance that can respond in an agile way to rapid and unanticipated change (Young 2017). In this context, governments retain a central role in achieving successful transformation of socioeconomic systems. Governments continue to have the capacity to adopt a collection of policies

from command-and-control regulations through to market-based measures in response to environmental problems. There are many examples where decisive government intervention has delivered major environmental benefit and transformed existing systems (e.g. the phase out of ozone-depleting substances, and the control of oil pollution from ships in the marine environment).

However, sometimes traditional governance approaches have their limits, including when what is needed is transformative change. Socio-ecological systems are increasingly complex in the variety of their components and their interactions so that it is not always possible to predict in advance what impact policy measures may have (Young 2017). Therefore, in addressing cross-cutting challenges, requiring whole-of-system change, there needs to be a willingness on the part of governments to engage in a reflective and experimental process of 'learning by doing', including regulatory experiments to test the feasibility of various approaches (e.g. Ostrom *et al.* 2007; Dryzek 2014).

This process of 'transformative learning' (ESCAP, ADB and UNDP 2018) can promote innovation by enabling experimentation through:

- i. creating and highlighting opportunities for communities to embrace new and alternative visions for serving human needs in a sustainable way;
- ii. enabling the participation of new actors that can provide more sustainable resources and services; and
- iii. transparently phasing out existing unsustainable structures.

Government has an important role in this process but there is a broader dynamic at play in which it is possible to achieve 'governance without government' (Ostrom 1990). Key to this process is social mobilization around shared values and a vision for just and sustainable systems.

### 17.2.1 Evaluating the effectiveness of policies for cross-cutting issues

On the basis of our continually improving understanding of environmental policymaking, it is possible to evaluate the effectiveness of environmental policies that address cross-cutting issues and their systemic drivers. This not only refers to their immediate or short-term performance in achieving their specific targets, but also to their potential to engender systemic transformation. There are two key criteria in this respect, namely the objective of the policy and the outcome of the transformation.

This chapter focuses on four cross-cutting global-scale sustainable development challenges and asks:

- i. What are the most urgent changes required in the system?
- ii. Which elements of the system do policies seek to address?
- iii. What has been done to date and how effective have these measures been?
- iv. What is the transformative potential of the policy approaches discussed?

In undertaking this assessment, four sustainability challenges are examined through the lens of specific case studies which illustrate policy responses in a range of different settings and

highlight challenges and opportunities for policy design and implementation. This chapter also provides broader insights on the effectiveness of cross-cutting environmental policies by examining policy-sensitive indicators.

## 17.3 Adapting socioeconomic systems to be more resilient to climate change

Climate change adaptation is a critical issue for coastal cities and Small Island Developing States (SIDS), as these are places where exposure to climate change impacts is increasing dramatically because of sea level rise. This is combined with dense populations and infrastructure along the coasts, rapid and often unplanned urbanization of low-lying areas, loss of ecosystems and environmental degradation, unsustainable management of natural resources, and lack of existing adaptive capacities.

Climate change adaptation needs to address both natural and human systems. Natural systems such as beaches, wetlands and coral reefs need to be protected by maintaining coastal ecosystems and processes and preventing erosion and flooding. Human systems – including settlements, industry, infrastructure, agriculture, fisheries, tourism, recreation and health – must be strengthened to become more climate-resilient. Adaptation strategies have recognized the special importance of safeguarding the most vulnerable groups, including Indigenous Peoples, women, children, those living with disabilities, and economically disadvantaged communities.

### 17.3.1 What are the most urgent changes required in the system?

The impacts of climate change differ across geographical locations, sectors and social groups. It particularly affects the lives, livelihoods and psychological well-being of the poor, vulnerable communities and people affected by disasters (Davis 2015; Dankelman 2016). Primary impacts include health risks related to temperature stress and extreme events leading to increased mortality and injury, internal and cross-border displacement, and infrastructure and economic loss and damages (Watts *et al.* 2015; Grimmer *et al.* 2016; Internal Displacement Monitoring Centre [IDMC] and Norwegian Refugee Council 2017). The secondary health impacts are mediated via the environment, including increased risk of climate-sensitive disease, which can be vector-, water- or food-borne. Tertiary impacts are socially mediated and include migration and conflicts (Watts *et al.* 2015). This requires adaptive responses to protect, preserve and promote human health and well-being.

#### **What elements of the system do the policies seek to address?**

Adaptation to sea level rise in coastal cities and SIDS seeks to address vulnerability to the following climate change impacts: coastal erosion, sea level rise, floods, and extreme events. They are generally categorized as 'protect', 'accommodate' or 'retreat':

- ❖ **Protection** of people and property by building higher seawalls, improving land-use management, developing new building codes to raise dwellings and infrastructure and reducing coastal erosion;
- ❖ **Accommodation** by changing the existing practices to make them more resilient to sea level rise, improving

infrastructure to increase absorption capacity of water bodies and wetlands, regulating water flow, introducing insurance; and

- ❖ **Retreat** by abandoning high-risk areas and relocating people away from the hazard.

Climate adaptation in coastal cities is still insufficient and may lead to increased risks in the future. Protecting existing populations and infrastructure has often led to even more development in high-risk areas, resulting in the accumulation of risk (Hallegatte *et al.* 2013). Climate adaptation programmes have not effectively dealt with multiple slow and rapid onset hazards, such as floods, droughts, tropical cyclones and sea level rise. They are often undertaken through sectoral programmes in, for example, agriculture, health and disaster management, rather than addressing the underlying causes of vulnerability. This has implications for human rights since persistent inequalities in terms of access to assets, opportunities, voice and participation, or discrimination mean poor and vulnerable communities lack adaptive capacity and are disproportionately exposed, and highly sensitive, to climatic hazards (United Nations 2016).

Some low-lying SIDS have experienced increasing flooding and significant coastal erosion and are expected to eventually become uninhabitable. Affected populations will be displaced and will need to migrate to other places or countries, with accompanying implications for their health and well-being (Schwerdtle, Bowen and McMichael 2018). Policy responses need to strengthen health systems to make them both climate-resilient and migrant-inclusive (Schwerdtle, Bowen and McMichael 2018). They also have to be integrated with other policy areas, such as border and labour market policies, and social and human rights protection.

### 17.3.2 What has been done to date and how effective have these measures been?

SDG 13 recognizes climate change as a critical issue and calls for urgent actions through strengthening resilience and

adaptive capacity, mainstreaming it into policies and planning, education and capacity-building. The 2015 Paris Agreement on climate change seeks to strengthen the capacity of countries to deal with the impacts of climate change and support action by developing nations and the most vulnerable countries. Support provided through strategies and mechanisms under the Paris Agreement include climate adaptation funds, technology transfer and climate insurance.

Global climate finance is US\$410 billion on average annually (Buchner *et al.* 2017). However, 93 per cent of this is spent on mitigation, while less than 5 per cent (US\$22 billion) is spent on adaptation (Buchner *et al.* 2017). Looking deeper into adaptation finance, less than US\$4 billion is spent on coastal protection, infrastructure and disaster risk management (Buchner *et al.* 2017). These are areas in greatest need if adaptation is to be strengthened in coastal cities and SIDS (Figure 17.1).

The United Nations Office for Disaster Risk Reduction (UNISDR), through the Sendai Framework for Disaster Risk Reduction (UNISDR 2015), recognizes the need for better integration of disaster risk reduction (DRR) and adaptation, since climate change increases the severity, intensity and frequency of disasters. Strengthened and more coherent actions towards the 2030 Agenda, the Paris Agreement and the Sendai Framework are being developed (UNISDR 2017). The focus in this area has moved from emergency management and response to reducing disaster risks and mainstreaming it into development.

Deaths from disasters have been dramatically reduced through early warning systems and better disaster preparedness and planning, while the current challenge is that the number of people affected and economic loss continues to increase (UNISDR 2017). The New Urban Agenda (United Nations Human Settlements Programme [UN-Habitat] 2016), coordinated by the United Nations Human Settlements Programme, is a global framework on sustainable urbanization to “make cities and human settlements inclusive, safe, resilient,

Figure 17.1: Climate finance on adaptation

Source: Buchner *et al.* 2017.

and sustainable". It is clearly recognized that cities, especially those on coastlines, are where some of the most vulnerable places and infrastructure are located (World Bank 2013). Within the framework of the Global Action Programme (GAP) on Education for Sustainable Development, United Nations Educational, Scientific and Cultural Organization (UNESCO) implements Climate Change Education (CCE) alongside Education for Sustainable Development (ESD) programmes (UNESCO 2014). CCE includes, among other issues, the science of climate change, social and human aspects, policy responses and sustainable lifestyles (UNESCO 2010). To ensure effectiveness of this policy, research shows that educational interventions are most successful when they focus on local, tangible and actionable aspects of sustainable development and climate change, especially those that can be addressed by individual behaviour (Anderson 2013).

The Pacific Adaptation to Climate Change (PACC) Programme is the first major climate change adaptation initiative in the Pacific region and is a partnership between several key regional and national agencies and communities in 14 Pacific island countries. It is coordinated by the Secretariat of the Pacific Regional Environment Programme (SPREP). An assessment of this programme calls for a more integrated approach to climate change, disasters and climate mitigation, and better management of information and data (Hay 2009). Policies related to climate-related migration are only just emerging. There are policy frameworks that have sought to integrate migration with border protection, livelihoods and social and human rights protection such as those developed by the Asian Development Bank (ADB 2012) and the Protection Agenda of the Nansen Initiative (2015), but implementation remains rare at the local level.

### 17.3.3 What is the transformative potential of the policy approaches discussed?

The policy approaches and case study presented (**Box 17.1**) reinforce the need for better identification of governance

for adaptation to address the complexities of the processes leading to and resulting from climate change impacts, and the underlying factors of vulnerability, and to build resilience and adaptive capacity. Governance of adaptation refers to the pattern that emerges from the processes of governing the social, political and administrative actors involved (Huiteima *et al.* 2016). Successful adaptation requires consideration of effectiveness, efficiency, equity and legitimacy to ensure the sustainability of development pathways into an uncertain future (Adger, Arnell and Tompkins 2005).

A transformative approach towards adaptation to climate change is increasingly proposed as an approach to deal with the impacts of climate change and can potentially offer changes in the way current adaptation is governed and implemented towards being resilient and sustainable. It is an approach that has the potential to mediate complexity, uncertainty and rapid change. Its identified characteristics include adaptive management, particularly in allowing learning and self-organization; addressing scale to increase a governance 'fit' between social and ecological aspects; and a polycentric governance system allowing redundancy and diversity through participation and collaboration (Brunner *et al.* 2005; Folke 2006; Brunner and Lynch 2010; Djalante, Holley and Thomalla. 2011; Chaffin, Gosnell and Cosens 2014). The transformative potential is reflected through innovation, experimentation, vision and space for new actors. Learning allows for experimentation to take place, visions to be generated and innovations to flourish (Taylor 2017). Actions are taken based on the best available knowledge and allowing for learning from mistakes and innovation to take place. Climate change education also contributes to capacity-building for decision makers and empowers people to implement their own adaptation strategies – for example, by equipping them to understand complexity, perceive risks and take into account indigenous knowledge (Nakashima *et al.* 2012; Blum *et al.* 2013; Monroe *et al.* 2017; UNESCO 2017; UNESCO 2018). Overall, the learning by different stakeholders increases transformation capacity.

#### Box 17.1: Case study: 'Living With Floods' programme in Viet Nam

This case study provides an example of policy approaches towards achieving effective adaptation, despite vast complexities in setting targets for achieving policy effectiveness (i.e. social equity/human rights, community participation, economic variability, differing capacities, and multilevel policy fragmentation). The Vietnamese approach could be considered as transformative because flood risk management policy changed from control to 'living with floods'. However, the effectiveness of the approach is limited in the face of increasing hazard risks in the Mekong Delta.

The 'Living with Floods' programme is part of the National Strategy for Natural Disaster Prevention, Response and Mitigation to 2020. It aims to accommodate rather than control floods through the use of semi-dykes that allow occasional and controlled floods, which in turn lead to better soil management. Residential clusters are protected from flooding by a full- and semi-dyke system. There are permanent residences and access to basic public services and facilities, such as schools and health clinics (Central Committee for Flood and Storm Control [CCFSC] 2012). Up to 150,000 households are involved with the programme. These households are chosen directly by local authorities in the Mekong Delta. Poor households are eligible for a long-term, low-interest government loan to fund the acquisition of their new home, while wealthier households can purchase housing plots directly. A weakness of the process is a lack of transparency with regard to the selection of households and the allocation of funds. The sustainability of the funding from the national government is uncertain. There is no community participation or consultation in the selection of relocation sites (Chun 2015).

Overall, though the programme moved communities out of harm's way, it has resulted in an increase in the economic vulnerability of most households due to loss of livelihoods. Economic and solidarity networks have been dislocated in the process, and most households report decreased income, as well as difficulties in repaying their debts (Chun 2015; Entzinger and Scholten 2016). Such detrimental outcomes are largely the result of lack of integration of environmental with other policy objectives, such as long-term economic sustainability. As a result, though the programme contains many positive aspects and intentions, it has led to decreased community resilience.

### 17.3.4 Indicators

Indicators play a critical role in the monitoring and evaluation of climate change adaptation. The indicators for SDG 13, 'Climate action', do not provide the most direct measurement of adaptation effectiveness. The level to which the CCA action contributes to achieving SDG 5 (achieving gender equality and empowering women and girls) and SDG 10 (reducing inequality within and among countries) are also important indicators of success.

Scientific frameworks for measuring vulnerability, resilience and adaptive capacities along with indicators have been developed (e.g. Cutter, Boruff and Shirley 2003; Turner *et al.* 2003; Wisner *et al.* 2004; Hinkel *et al.* 2012; Taylor 2017). Examples of indicators to measure effective adaptation efforts for coastal cities can include identifying the amount of land area known to have (in)sufficient infrastructure, reducing the number of residents living in floodplains or low-elevation coastal zones, or developing a network of communication channels in times of crisis or disaster. For SIDS, indicators for adaptation include measures to respond to decreases in available fresh water (drought-resistant vegetation, water-saving devices, establishing buffer zones to protect catchment areas), prevention and removal of maladaptive practices (amend policies that lead to destruction of mangroves, laws preventing recycling of water, or allowing building in vulnerable areas), and address impacts of climate change on biodiversity and land degradation (land-use models for efficient farming, sustainable fishing practices, raising community awareness) (United Nations 2015).

Some considerations for achieving more transformational change – and ensuring effective adaptation measures – include consideration of scale (using a landscape- or basin-scale approach, and distinguishing between short-, medium- and long-term strategies), community participation, novel approaches to adaptation (e.g. the use of crop insurance in developing countries, building market resilience to climate change), and those that transform places or shift locations (artificial islands combined with relocation, and new institutions and funding mechanisms for reduced vulnerability) (Kates, Travis and Wilbanks 2012). Vulnerability and capacity assessments (VCA) together with climate risk screening and assessment are necessary to ensure that future development programmes consider impacts of climate change – see, for example, the International Federation of Red Cross and Red Crescent Societies VCA (International Federation of Red Cross and Red Crescent Societies n.d.), and Climate and the Disaster Risk Screening tool from the World Bank (World Bank 2018), or UNDP Report on stocktake of climate risks screening tool (Olhoff and Schaer 2010).

## 17.4 Creating a sustainable agrifood system

One of the best illustrations of the need to reduce uncertainties in the face of climate change is found in the agrifood system. The following section looks at some of the possibilities for transformation in this sector.

### 17.4.1 What are the most urgent changes required in the system?

The agrifood system is responsible for significant environmental impacts including greenhouse gas emissions, habitat destruction and biodiversity loss, and pollution of air and water resources. These environmental costs are compounded by the inefficiency of the agrifood system. According to one study, 62 per cent of the energy (in terms of kcal) harvested as crops and other biomass, is lost or wasted after accounting for losses from food waste, trophic losses from livestock, and human overconsumption (Alexander *et al.* 2017). Achieving the SDGs requires urgent action to reduce the system's environmental footprint and increase its overall efficiency and resilience. A whole-system approach is needed, including action to intensify agriculture sustainably, reduce food losses and greenhouse gas emissions along supply chains, and tackle wasteful consumption patterns including high consumer food waste and overconsumption of animal products.

Policies that shape the agrifood system can be broadly categorized in terms of production, processing and distribution, and consumption. Agricultural policies are typically focused on supporting farmers rather than on providing incentives for improved environmental outcomes. Moreover, reforming subsidy regimes often presents governments with significant political challenges. To the extent that they encourage production without accounting for environmental impacts, many agricultural policies exacerbate environmental problems (e.g. subsidies for fertilizer, water or energy use). Few governments have developed strategies for reducing greenhouse gas emissions from the agriculture and land-use sector (with the notable exception of forests); to date, no national government has fully included agriculture in a carbon pricing scheme.

Trade policies for agricultural commodities typically avoid explicit environmental criteria in order not to contravene World Trade Organization (WTO) rules that prevent governments from distinguishing between 'like' products, while regulations are concerned primarily with human health. Incentives to reduce food waste and losses have been eroded by low and declining real food prices (Benton and Bailey in press) and, despite increasing government intervention to shape consumption patterns for public health reasons (e.g. to reduce consumption of sugar, salt and trans fats), there is little policymaking that encourages sustainable diets (Garnet *et al.* 2015).

In sum, transforming the agrifood system to achieve the SDGs requires that the environmental footprint of agriculture is dramatically reduced, food losses and waste are drastically curtailed, and populations adopt healthier and more sustainable diets. This in turn requires a shift in policymaking to:

- i. incentivize farmers to reduce negative environmental externalities, including greenhouse gas emissions, and create positive externalities, such as enhanced biodiversity or other ecosystem services;
- ii. tackle food losses and waste along the entire value chain; (**Box 17.2**) and
- iii. encourage the adoption of healthy and sustainable dietary patterns.

#### 17.4.2 Which elements of the system do policies seek to address?

##### **The polluter pays principle**

Environmental impacts are a common symptom of agricultural policies that support farmers to maximize food production. Policy reforms designed to eliminate these impacts can take different forms, but essentially seek to ensure that the 'polluter pays'. Examples include taxes on fertilizer and pesticide use (rather than subsidies), water pricing schemes and regulations requiring farmers to build and maintain storage infrastructure for animal slurry.

While there is considerable national experience in applying the polluter pays principle to carbon emissions in the energy sector via emissions trading schemes and carbon taxes, agriculture remains excluded from such initiatives. Monitoring, reporting and verification of emissions in agriculture is considerably more complex and costly than for energy, because greenhouse gas emissions occur at the landscape scale according to farming practices and agroecological context. Nevertheless, this does not necessarily present an insurmountable barrier. For example, in New Zealand, the agricultural sector reports its greenhouse gas emissions without being part of the national emissions trading scheme, indicating that it is possible to quantify and account for emissions from agriculture.

##### **The beneficiary pays principle: payments for ecosystem services (PES)**

Several governments have introduced economic policy measures to encourage environmentally sensitive farming practices. The basic intention is to incentivize and reward those agricultural producers who take steps to minimize their environmental impacts or to deliver non-productive outputs (often termed 'payment for ecosystem services' (PES)), and to disincentivize and penalize those who do not (Meyer *et al.* 2014; Tanentzap *et al.* 2015). One such example is agricultural producers' participation in carbon markets by selling offset credits generated by specific projects to reduce emissions (Garnett 2012). In this case, rather than being penalized for emitting greenhouse gases as regulated entities under a carbon pricing scheme, farmers are paid for avoiding emissions.

The market for PES is growing and is now estimated at between US\$36 billion and US\$42 billion a year, including payments from non-governmental and private buyers. The largest areas include payments for watershed management and biodiversity, with the vast majority of payments for emissions reductions coming from forest projects (Salzman *et al.* 2018). Although by no means a negligible sum, these transfers are modest compared with conventional agricultural support, which totalled just under US\$230 billion in 2017 in Organisation for Economic Co-operation and Development (OECD) countries and a similar amount in China (US\$204 billion) (Organisation for Economic Co-operation and Development [OECD] 2018).

##### **Consumer education**

Consumer education, based on the concept of education for sustainable development, can enable consumers to understand how their individual dietary choices and habits influence social, economic and environmental development, to envision sustainable dietary choices and habits, and to adopt

them (Fischer and Barth 2014; UNESCO 2017). For example, education can make meat consumers more aware of their own unsustainable consumption (Spannring and Grušovnik 2018).

##### **Dietary guidelines**

Governments typically use national guidelines to inform populations about good nutrition and healthy eating. In recent years, a small number of governments have begun to include environmental considerations in the guidelines they publish (see below for a discussion). National guidelines are unlikely to lead to widespread changes in eating habits on their own, but they can provide a basis for subsequent policymaking, and as such may constitute an important first step on the path to more concerted policy action (Bailey and Harper 2015, Garnett *et al.* 2015).

##### **Labelling and certification**

Schemes that provide consumers with assurance that a particular food meets certain environmental criteria have become increasingly common in developed country markets. These initiatives tend to be multi-stakeholder in their origins rather than policy led, often emerging from cooperation between the private sector and civil society; however, where sufficiently robust they can provide a basis for subsequent policymaking.

##### **Public procurement**

In many countries, public procurement of food can represent an appreciable share of market demand, hence public procurement policies in this area require suppliers to meet certain environmental standards and have the potential to drive wider change in the food system.

##### **Consumption taxes**

The costs of negative environmental impacts can also be incorporated at the point of consumption. To date, consumption taxes have been used to address health externalities associated with overconsumption of foodstuffs such as sugar. However, applying an emissions tax on foods at the point of consumption may be preferable to pricing emissions at the point of production. Although the latter approach may more accurately internalize the impact, consumption taxes may still be a better option because:

- i. the costs of monitoring emissions in agriculture are high;
- ii. the mitigation opportunities beyond reducing output of emissions-intensive foods are limited; and
- iii. the opportunities for consumers to switch from foods of high emissions intensity to low emissions intensity are high (Wirsenius, Hedenus and Mohlin 2011).

Nonetheless, consumption taxes do not need to be blunt instruments with blanket rates applied indiscriminately across a product category. Differentiation between production and supply practices within a product category (e.g. by using disaggregated life cycle analyses) would allow for more nuanced reflection of externalities and incentivize the adoption of more sustainable practices, as well as consumer-switching to more sustainable products, within – as well as across – food categories. The transformative potential of consumption taxes could be high. It is estimated that worldwide emissions taxes on foods could save around 1 gigaton of CO<sub>2</sub> equivalent per year in 2020 and result in net health benefits at the global level due to reduced consumption of meat, although this would entail distributional impacts that governments would need to

manage with compensating policies (Springmann *et al.* 2016). No government has yet imposed an emissions tax on food, although some have implemented consumption taxes on certain foods for public health reasons.

#### 17.4.3 What has been done to date and how effective have these measures been?

##### **Production: economic incentives for ecosystem services**

Payments for ecosystem services may pertain to additional conservation or sustainability practices to which agricultural producers commit voluntarily, or they may offer financial compensation to farmers whose income or production capacity is limited by the requirements of existing regulation (often referred to as 'cross-compliance') (Meyer *et al.* 2014).

In the European Union (EU), both approaches have been used under the Common Agricultural Policy (CAP). Agri-environment measures (AEMs) under Pillar II of the CAP are area-based mechanisms that occupy a middle ground between entirely voluntary schemes and direct compensation for cross-compliance. Funded jointly by the CAP and national authorities, AEMs are intended to encourage farmers to improve soil quality, use water resources more efficiently, reduce polluting inputs, and increase agricultural biodiversity. The majority of AEMs are action-based, compensating farmers for the activities they undertake, but more recently results-based AEMs have been introduced, with increased conditions and payments dependent on achieving desired environmental outcomes. These AEMs are less prescriptive with regard to management practices, are more cost-effective, and can encourage innovation (Illes *et al.* 2017). Generally, PES programmes applied nationally or internationally will be better able to maximize these benefits if they are flexible enough to be tailored to the unique conditions of local institutional and environmental contexts (de Blas *et al.* 2017).

As part of the CAP 2014-2020 Reform, the EU introduced a new form of direct payment support in 2015. The 'Greening Payment' was introduced under Pillar I of the CAP to supplement existing cross-compliance rules and oblige farmers who receive the direct payment support to meet three ecosystem service criteria. Initially the greening approach

would provide "simple, generalized, annual and non-contractual payments" (European Commission 2011) that would create climatic and environmental benefits and permit Pillar II financial resources to be better spent on increasing the ambition of the agri-environment schemes (AESs). Relative to the original proposal, however, greening – as implemented – has affected a reduced area of farmland and encouraged fewer farmers to change their farming practices (Hart, Buckwell and Baldock 2016). Its effectiveness is also uncertain because ecosystem services usually need to be provided at a larger scale than permitted by agricultural management, requiring coordination across landowners (Benton 2012).

Although it is too early for a full end-of-project evaluation, there are a number of analyses that point to the greening programme having a limited impact and poor cost-effectiveness, given that it accounts for a sizeable proportion of the overall CAP budget (European Commission 2016; Gocht *et al.* 2016; Hart, Buckwell and Baldock 2016; Buckwell *et al.* 2017; OECD 2017).

##### **Consumption: convincing stakeholders**

There are early signs of sustainability criteria being incorporated into dietary guidelines, in an effort to convince consumers to adjust their consumption patterns to improve nutritional outcomes and to reduce the environmental burden. A recent global review of national dietary guidelines (Fischer and Garnett 2016) found that only four countries had so far included sustainability concerns into their food-based dietary guidelines (Brazil, Germany, Qatar and Sweden). Although most sustainability guidelines to date are health-oriented, reflecting the fact that their creation tends to be led by health ministries, and the link between behavioural change and influence from guidelines is challenging to demonstrate, more widespread inclusion of sustainability concerns in nutritional guidelines could serve to encourage policies that transform consumer demand.

#### 17.4.4 What is the transformative potential of the policy approaches discussed?

Table 17.1 shows the transformative potential of some of the policy approaches discussed above as 'high', 'medium' or 'low'. These qualitative categories are posed as questions to

#### **Box 17.2: Case study: Food losses and waste – multiple policy approaches in Japan**

In Japan, multiple policy approaches are used to reduce food waste and losses, such as legislative targets, providing information to educate stakeholders, voluntary codes of conduct, and enabling new institutional arrangements. Those discussed here are primarily concerned with reducing waste in downstream sectors of the supply chain (processors, retailers, hospitality, consumers), but policy approaches are equally required to tackle upstream post-harvest losses. Policies to control and recycle food loss and waste have been implemented since 2000 under the Food Recycling Law, which obligates food manufacture, distribution and catering businesses to recycle waste materials and requires all businesses generating more than 100 tons of food waste annually to report on their waste generation and recycling activities (OECD 2014).

Following generally successful implementation – the majority of food waste associated with business activities is now recycled (as high as 95 per cent in the food manufacturing industry in 2011, though only 23 per cent in the catering industry in the same year [OECD 2014]) – food waste reduction is now a priority over reuse and recycling. Target values for controlling food waste generation have been established for 26 industry groups over the period of 2014-2019. Where unilateral action is challenging for businesses, such as waste resulting from returned goods and excess inventory, the Japanese food industry has formed a working group to address business practices such as changing delivery deadlines, best before date use standards, and labelling methods.

Levels of consumer food waste have changed little in recent years and this is now a priority area; it features prominently in the campaign introduced as a collaboration between six government ministries in 2013, 'No-Food-loss Project', aimed at increasing awareness and changing behaviour related to food losses at all stages of the supply chain (Food and Agriculture Organization of the United Nations [FAO] 2014).

**Table 17.1: Agricultural system components, production, food loss and waste, consumption**

| <b>Agrifood system component</b>                                                                                                                                                                  | <b>Production</b>                                                                                                                                                                                                                                                                     | <b>Food losses and waste</b>                                                                                                                                                                      | <b>Consumption</b>                                                                                                                                                                                                                                                                                                          |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Policy approach</b>                                                                                                                                                                            | Economic incentives for ecosystem services: payments for ecosystem services                                                                                                                                                                                                           | Various policy approaches, including food recycling laws                                                                                                                                          | Convincing stakeholders: guidelines for sustainable, healthy diets                                                                                                                                                                                                                                                          |
| <b>Promote innovation, including social and institutional innovation, that will not only improve existing approaches, but also entail completely new approaches to meet the needs of society?</b> | Medium<br>Payments for ecosystem services (PES) can be implemented in ways that are innovative – e.g. reforming existing subsidy regimes or developing new market mechanisms.<br>Depending on the design and context, PES may create incentives for actors to develop new approaches. | Medium to high<br>Mandatory targets encourage innovation across businesses in the supply chain to meet the requirements                                                                           | Low<br>May inform innovation in wider policymaking, but not intrinsically or in isolation. For example, regulatory nutritional labelling may encourage food manufacturers to reformulate products, but in isolation of wider regulation or policy, guidelines, are unlikely to promote innovation (Bailey and Harper 2015). |
| <b>Enable experimentation, including regulatory experiments to test and demonstrate the feasibility of alternative configurations?</b>                                                            | Medium<br>The Common Agricultural Policy (CAP) example demonstrates that PES can enable regulatory experimentation through changing of subsidies.<br>Outcome-based payments are more likely to encourage experimentation among the recipients, rather than activity-based payments.   | Low to medium<br>Regulation is unlikely to drive experimentation.<br>Does not proactively drive businesses to experiment, but may create conditions in which they are encouraged to make changes. | Low<br>Does not always enable experimentation, but could be the basis for subsequent regulatory experimentation.                                                                                                                                                                                                            |
| <b>Facilitate new and alternative visions for serving human needs in a sustainable manner?</b>                                                                                                    | High<br>Depending on implementation, this approach could pay farmers to deliver new visions for agriculture and landscapes.                                                                                                                                                           | High<br>Provides clarity on a low food waste future with expectations of high recycling rates.                                                                                                    | Medium<br>Shows a vision but does not aid the delivery of such a vision.                                                                                                                                                                                                                                                    |

| <b>Organize the phase out of existing unsustainable structures?</b>                                                                                                                               | Low<br>Focuses on reforming the existing businesses.                                                                                                                                                                                                                                  | Medium<br>Reduces the volume of material going to landfill and the viability of existing waste chains, but does not necessarily fundamentally reorganize these structures.                        | Low<br>Guidelines alone do little to reorganize existing structures – it requires accompanying policy measures to do so.                                                                                                                                                                                                    |

show the potential of the approach rather than the specific implementation of the instruments. How, and under what circumstances, each approach is implemented in any given situation will largely determine how transformative the outcomes are in that particular instance.

#### 17.4.5 Indicators

Many existing indicators – such as agricultural emissions from different farming sectors – provide valuable information on the environmental sustainability of different parts of the food system, and others are still under development (e.g. SDG indicator 2.4.1 'Proportion of agricultural area under productive and sustainable agriculture'). However, these indicators are

usually focused on productive aspects of the food system and tend not to show the efficiency or transformation of the system as a whole. To achieve this we propose a new policy-sensitive national-level indicator for the sustainability and nutrient efficiency of national dietary outcomes: dietary health and sustainability. The dietary health and sustainability indicator would be based on existing annual data series and measure the gap between national consumption patterns and national healthy and sustainable nutritional guidelines. However, as already noted, very few countries currently have nationally defined guidelines on the composition of healthy and sustainable diets. In the absence of such guidelines, alternative global values could be derived from the forthcoming recommendations of the EAT-Lancet Commission on Food,

Planet, Health, which intends to reach scientific consensus on what defines a healthy and sustainable diet (EAT-Lancet Commission on Food, Planet, Health 2018; Springmann *et al.* 2018).). The EAT-Lancet Commission recommendations could also be the basis of an aggregate global indicator.

If reliable national data on consumption are unavailable, the dietary health and sustainability indicator would use existing FAO Food Balance Sheet (FBS) data that include annual estimates of national food supplies per capita for each primary commodity and a number of processed commodities that are potentially available for human consumption. However, the FBS data are somewhat crude. The categories are summed to a high level, limiting the level of detail at which analysis can be conducted. Nor do they capture the nature of the food consumed, including whether it is heavily processed – which can have important health implications. Given these shortcomings, governments would be encouraged to gather more accurate data on national consumption patterns as well as to develop nationally appropriate guidelines for healthy and sustainable diets that better reflect the national context.

**Table 17.2: Recommended intake for a healthy and sustainable diet**

| Hypothetical national (or EAT-Lancet Commission) recommended intake for a healthy and sustainable diet | Dietary Health and Sustainability indicator value (annual, national value)   |
|--------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------|
| X g/capita per day of fruit and vegetables                                                             | Vegetable intake: (+/-) Y per cent of healthy and sustainable levels         |
| X kcal/capita per day of cereals and starches                                                          | Cereal and starch intake: (+/-) Y per cent of healthy and sustainable levels |
| X kcal/capita per day of oils and fats                                                                 | Oil and fat intake: (+/-) Y per cent of healthy and sustainable levels       |
| X g/capita per day of meat                                                                             | Meat intake: (+/-) Y per cent of healthy and sustainable levels              |
| X g/capita per day of dairy                                                                            | Dairy intake: (+/-) Y per cent of healthy and sustainable levels             |

Food-groupings of national food intake or supply data would be measured to show the proportion by which they exceed or fall short of national guidelines or EAT-Lancet Commission recommended daily intakes for corresponding food groups:

$$[(\text{intake value} / \text{recommended intake}) - 1] \times 100$$

A value of zero represents 'ideal' consumption, negative values represent underconsumption and positive values show overconsumption. For example, if there were recommended intake values for the food groups in **Table 17.2**, the dietary health and sustainability indicator would express each country's supply in relative terms (**Figure 17.2**).

The FBS data show the quantities of food available to the population after accounting for exports and imports, other uses (livestock feed, seed, non-food uses), and losses during storage and transportation. Therefore, the dietary health and sustainability indicator would provide a useful high-level picture of the performance of policies and measures across the entire food system, including actions to reorient agricultural production, trade measures, actions to reduce pre-household waste, and nutritional policies. It would provide an integrated measure of the agrifood system's contributions to progress against multiple SDGs.

Since this proposed dietary health and sustainability indicator is consumption-based, it would not fully reflect the impact of agricultural policies in countries that are large net exporters of agricultural goods, or which produce significant proportions of non-food agricultural products. For example, a country's consumption may appear to be healthy and sustainable, but if consumption is largely based on imported foods, this provides no indication of the sustainability of the agricultural system in that country. On a global basis, however, the dietary health and sustainability indicator would provide an aggregate indication of the sustainability of food production.

## 17.5 Decarbonizing energy systems

The previous section discussed how agricultural policies tend to focus on supporting farmers rather than providing incentives for improved environmental outcomes. In the complex agrifood system reducing energy use will also play an important role. This section explores the transformative potential that will come from decarbonizing all energy systems.

**Figure 17.2: Health and sustainability of country X's dietary intake**

### 17.5.1 What are the most urgent changes required in the system?

Greenhouse gas emissions generated from energy use are a major driver of global climate change. Reducing the carbon footprint of global energy use requires integrated approaches that combine measures to:

- reduce energy use;
- lower the greenhouse gas intensity of end-use sectors;
- decarbonize energy supply; and
- reduce net emissions and enhance carbon sinks.

There are important co-benefits of these measures, including:

- reduced costs;
- greater energy security; and
- human and ecosystem health.

Near-term reductions in energy demand are cost-effective climate mitigation strategies, giving more flexibility for reducing carbon intensity in the energy supply sector, protecting against supply-side risks, and avoiding lock-in to carbon-intensive infrastructures. Delayed scaling up of low-carbon energy systems would make limiting warming over the 21st century to below 2°C very difficult to achieve, and will require much bolder actions such as a larger reliance on carbon dioxide removal in the long term (Intergovernmental Panel on Climate Change [IPCC] 2014).

### 17.5.2 What elements of the system do the policies seek to address?

Long-term planetary sustainability requires both policy and technological innovations to bring about changes in the choice of fuels, the way they are produced and consumed, and the way in which resources are impacted systemically at every stage of the energy system (Figure 17.3).

Major areas of policy intervention in energy systems, which relate to the SDGs (especially SDG 7) are decarbonization measures that aim to substitute fossil fuels with clean(er) or renewable alternatives, implement efficiency measures that can provide the same service while using fewer resources, enhance access to other energy forms and services, apply land-use and urban planning which considers energy integration (e.g. distributed energy, smart grids, electric vehicle charging networks), and minimizes waste and lock-in of particular technologies by existing systems based on fossil fuels.

### 17.5.3 What has been done to date and how effective have these measures been?

Mechanisms to address these challenges include carbon pricing (cap and trade systems, carbon taxes and other economic instruments such as fuel taxes, different subventions to renewable energy), regulatory approaches (energy efficiency standards, command-and-control, mandatory decommissioning of old plants), information programmes (addressing behaviour, lifestyle and culture), and addressing administrative and political barriers (including through international cooperation) (IPCC 2014). Policy interventions also include research, development and demonstration (academic funding, grants, incubation support, research centres, public-private partnership, prizes, tax credits, voucher schemes, venture capital, soft and convertible loans), fiscal incentives (grants, energy production payments, rebates, tax credits and reductions, changes in depreciation), public finance (investments, guarantees, loans, procurement), regulations (quantity or quality driven, e.g. renewable portfolio standards, tendering and bidding, feed-in tariffs, green purchasing and labelling, net metering, priority to access to networks or dispatch) (Mitchell *et al.* 2011; International Renewable Energy Agency [IRENA] 2016; International Council for Science 2017; United Nations Industrial Development Organization [UNIDO] 2017).

Figure 17.3: An illustrative energy system

Source: Adapted from International Energy Agency (IEA) (2017)

Combined policies for renewable energy and efficiency form the basis of a low-carbon transformation for the global energy matrix. The diffusion, penetration and integration of these policies determine how effective this change can be. The effectiveness of these policy innovations depends on national capacities for action, on the demand for appropriate approaches applied by 'front-runner' countries, on the international policy transfer process, on the enabling conditions for such transfer, and whether policy models are developed at an early stage of the diffusion process to guide other countries (Kern, Jorgens and Jänicke 2001).

#### 17.5.4 What is the transformative potential of the policy approaches discussed?

Building on the momentum created by the 2015 Paris Agreement, a total of 117 Nationally Determined Contributions were submitted, of which 55 included targets for increasing the use of renewable energy, while 89 made reference to renewable energy more broadly (Renewable Energy Policy Network for the 21<sup>st</sup> Century [REN21] 2017). In 176 countries, targets for renewable energy were a primary means by which governments expressed their commitments. As of 2016, nearly all countries directly supported renewable energy technology development and deployment through some mix of policies.

The other pillar of sustainable energy is efficiency. As shown in **Box 17.4**, improving energy efficiency can generate energy savings and mitigation of associated carbon emissions, encouraging large-scale investment in a competitive and innovative manufacturing industry.

Policy support for renewable energy has been focused mostly on power generation (as in the case in **Box 17.3**), although implementation for such policies has slowed in recent years in response to tightening fiscal budgets and/or falling technology costs, with auction-based procurement now being a preferred policy approach. In 2014-2016, no new renewable portfolio standards or feed-in (tariffs and premiums) policies were introduced at the national level. However, support for new technologies is still an important driver for transformational change, and lessons from the past can be learned to allow an urgently needed scaling up to address climate change and other socio-ecological challenges.

On the demand side, electric efficiency tackles the purpose of environmental impact mitigation benefits along with improved energy access to cleaner energy. The India case (**Box 17.4**) resulted in spurring large-scale investment in manufacturing, improved standards, raised consumer awareness, generated employment and improved prospects for education, enhanced livelihoods and health.

#### 17.5.5 Indicators

Energy production and consumption are one of the most tracked indicators, due to the heavy cost implications and the geopolitical implications of the energy sector. Because of this it is known that in 2015 the world consumed 13.65 billion metric tonnes of oil equivalent, with energy demand having doubled over the previous 40 years. Of this energy, 81.4 per cent was provided by fossil fuels (coal, oil and natural gas) emitting 32.3 billion tons of carbon dioxide (IEA 2017).

#### Box 17.3: Case study: Support for renewables in Germany: feed-in tariffs

The German Feed-in Tariff (FIT) policy under the 2000 Renewable Sources Act (Erneuerbare-Energien-Gesetz, EEG) was a remarkable intervention towards low-carbon technology (LCT) diffusion. The main policy design elements were: (i) guaranteed access to the grid for LCTs (purchase obligation); (ii) stable and long-term power purchase agreements (long payment duration); (iii) prices reflecting the varying costs of different LCTs (fixed tariffs with some particularly strong incentives for given technologies such as solar photovoltaics [PV] and onshore wind); and, more recently, (iv) expansion corridors for specific LCTs, limiting capacity additions and household costs. As a proxy for technology diffusion, installed capacity (2016) was 45.4 GW for onshore wind, 4.2 GW for offshore wind and 41.3 GW for solar PV (IRENA 2016). A 2016 amendment to the Act shifted the focus to large investors, with an auctioning scheme according to energy source, plant size and plant location. Design elements proved remarkably stable while flexible. Fixed tariffs led to a surge in deployment and the formation of a domestic solar industry.

In combination with the uptake of onshore wind, and farmers and house-owners profiting from the EEG's conditions, a powerful group of advocates evolved. Driven by a discussion about 'affordability' of continued LCT support schemes, the 2016 amendment replaced the FITs with an auctioning scheme, still technology-specific but aimed at existing large investors rather than at small ones that previously played a large role in the EEG. It was a blueprint for other countries which led to policy diffusion and learning (by doing and by using), ultimately driving down costs on a global scale faster than anticipated. Success was based on long-term guaranteed support and inter-technology differentiation, plus a relatively stable basic policy rationale, adjusted to changing conditions (e.g. cost changes) and minimizing windfall profits. Policy predecessors (1991 onwards) were already established in a highly regulated sector, ensuring fast decision-making, strong support and positive feedback loops. The Fukushima disaster and resulting commitment to nuclear phase-out also helped in creating long-term security in terms of LCT business models. Small decentralized project stakeholders were empowered, as was the domestic industry, in clusters around specific LCTs (wind, solar PV and others).

Household affordability was addressed through the introduction of caps for specific LCTs and factoring in social and environmental costs. Key actors were utilities and industry associations, environmental groups, political parties, and ministries. Some constraining complexity of the energy policies, the existing locked-in technology (fossil fuels, energy consumption), and badly designed policies (e.g. carbon pricing under the EU Emissions Trading System). Later, Fukushima changed the politics in the energy sector, and opponents criticized incentives due to cost inefficiency. However, even with the latest amendment replacing FITs by auctions, technology-specificity remained as a design element. The general public considered the policy necessary and effective (in terms of job and value creation, achieved technology innovation, disruption of incumbent systems, stable investment environment for LCTs) particularly during the first years that the policies were in effect.

## Box 17.4: Case study: Demand-side management in India: affordable LED lights for all

The 2013 UJALA (Unnat Jyoti by Affordable LEDs for All) programme in India focused on the demand-side management of residential electricity. Implemented by Energy Efficiency Services Limited (EESL) with support from the Ministry of Power and local manufacturers, efficient LED lamps were distributed to domestic consumers at one-third of the market price. Having demonstrated success within 2-3 years, it covered high upfront costs for a large consumer base: the poorer sections of society. More than 260 million LEDs were sold, with annual savings of over 30 GWh of electricity, mitigation of around 3 million tons of CO<sub>2</sub> (2015) and one of the world's fastest reductions in LED retail market prices (US\$12.28/bulb to US\$3.07/bulb over 2012-2016).

The sale of new appliances provided energy savings, improved access to modern energy services, growth of domestic manufacturing to an internationally competitive business, better efficiency standards, and a growth in accredited testing laboratories and better consumer awareness. It was an example of low-carbon technology deployment, which created a large market (LED bulbs emerging as the preferred lighting option) using a bulk procurement model, with a technological advancement based on the idea of encouraging business models that could help in meeting the low-carbon emission targets at a faster rate. Domestic manufacturing has increased, and efficiency standards improved with market confidence in the product. Accredited testing laboratories have grown and consumer awareness has increased.

Empowered families had substantial money savings (over US\$0.25 billion/year; household electricity bills fell 15 per cent), plus resource savings, emissions mitigation (about 3 million tons CO<sub>2</sub>/year), improving quality of life, promoting productivity and local prosperity, and expanding energy access. Such a bulk procurement model allowed for a massive technology advancement. UJALA is an international demand side management showcase, being applied in the second largest world market (worth US\$0.33 billion/year and growing) and more recently replicated in Malaysia, also with attempts to cover more appliances, sectors, companies and regions (Chunekar, Mulay and Kelkar 2014; ET Energy World 2017; Energy Efficiency Services Limited (EESL) and IEA 2016; Sundaramoorthy and Walia 2017; India, Ministry of Power 2018a; India, Ministry of Power 2018b).

Despite a slowing trend, global energy demand may still expand by 30 per cent between 2017 and 2040 according to the International Energy Agency (IEA 2018). This amount is the equivalent of adding another China and India to today's global energy demand. At the same time, universal access to electricity remains a challenge. Large-scale shifts in global energy systems are due to the rapid deployment and falling costs of clean energy technologies (chiefly renewables but also natural gas), the growing electrification of energy, and the shift to a more services-oriented economy. Renewable energies are expected to meet 40 per cent of the increase in primary demand, capturing two-thirds of global investment in power plants to 2040 as their costs drop, enabling policies to continue to support them, and the transformation of the power sector is amplified by millions of electricity end users investing directly in distributed solar photovoltaics, with an increasing share of smart connected devices and other digital technologies. Electrified transport will grow, pushing the global electric car fleet to 280 million by 2040, from the present 2 million. Global investment in electricity overtook oil and gas investment but the challenge of decarbonizing the global power supply remains. Natural gas plays an important role in replacing oil and coal, with 80 per cent of the projected growth in demand for natural gas taking place in developing economies and the shift towards a more flexible, liquid, global market (IEA 2018).

## 17.6 Towards a more circular economy

The three previous sections of this chapter illustrate some of the effects of a linear economic system on the global environment. In this section, we analyse the use of materials/resources throughout the value chain from extraction to waste in the prevailing economic systems and examine approaches for developing a circular economy.

### 17.6.1 What are the most urgent changes required in the system?

For several centuries, most societies have pursued development using a linear economy model, where the majority of resources are extracted, processed, converted to products (some of which have a very short lifespan) and are then disposed of after use (commonly referred to, as the "take, make, waste" process). Within this economic model, only a small percentage of materials is reused or recycled (the exception being commodities like iron and gold). Instead, at the end of life they are considered waste and there is often a high price, financially, socially and environmentally to dispose of this waste.

## CIRCULAR ECONOMY

© Shutterstock/petovarga

The linear economy assumes that there will always be an abundant supply of raw materials and unlimited capacity to dispose of waste in the natural environment. However, as can be seen from Part A of this report, human societies cannot continue to operate in this way if we want to meet the demands of a growing population, preserve the health of the planet, and ensure that future generations are able to prosper. Continuing to extract natural resources such as minerals using this model implies an increasing environmental impact to extract ever diminishing ore grades. The example of fossil fuel resources shows that the capacity of ecosystems to absorb emissions is limited. Within the sustainability framework, some resources are finite and current levels of consumption are not compatible with reaching the SDGs. An alternative is to build sustainable economies that recognise the value of natural resources through a 'circular economy' (Figure 17.4).

The components and strategies of a circular economy model were first identified in the early 1980s and refined in following decades (Stahel and Reday-Mulvey 1981; Ayres 1994). These earlier models referred only to waste management – collection, separation, recycling, reuse. Today, there are many circular economy strategies being applied by individuals,

businesses and governments. These can go beyond dealing with waste to include better product design, reduced consumption and sustainable materials management. The common aim is to use resources in the most efficient way for the longest possible time. The resources circulate through various processes, being reused, repaired, redesigned or remanufactured, which reduces the need for new raw materials and minimizes waste (Figure 17.4). When faced with persistent environmental problems such as climate change, resource scarcity and biodiversity loss, adopting resource circularity makes sense; however, society has been slow to adopt this model or has simply failed to take the actions necessary for large-scale change.

Speeding up the transition to a circular economy involves a large shift in business and consumer thinking, demanding the adoption of sustainable production and consumption processes. Fuenfschilling and Truffner (2014) identify breaking down long-standing rigid and interdependent system structures as the main challenge. The difficulty stems from having to enact large-scale socio-institutional change, which may require radical new ways of thinking and adjustment to normal customs and beliefs (Potting *et al.* 2017). Moving from

**Figure 17.4: Building a circular economy**

Ultimate circularity ..... Circular economy goes beyond recycling

Source: Based on Stahel (2016) and Potting *et al.* (2017).

the established way of thinking involves the development of new laws and policies, which need revised, redesigned or new business models that integrate industries and incorporate a longer-term perspective, the internalization of the environmental and social costs of extraction, production and disposal, innovative technologies, and changes in consumer use patterns. Actions that can contribute to accelerated transformation have been outlined by the Government of the Netherlands (2016) and include the following.

- ❖ Decreasing demand for raw materials by increasing the efficiency of raw material use in the supply chain.
- ❖ In instances where raw materials are required, replacing fossil-based, scarce and non-sustainably produced raw materials with sustainably produced, renewable and readily available raw materials.
- ❖ Developing new innovative low-carbon production methods and smart product design.
- ❖ Promoting thoughtful consumption (e.g. reuse, smart design, extension of product life through design and repair, use of secondary and recycled materials, sharing economy).

Circular economy strategies have also been developed by Germany, Finland, Denmark and Slovenia. France, Italy and Spain have their road maps developed as well.

The circular economy promotes a production and consumption model that includes restoration and regeneration where possible (Ellen MacArthur Foundation 2015; Smol, Kulczycka and Avdiushchenko 2017). It ensures that the worth of products, materials, chemicals and resources is maintained in the economy at their highest utility and value for as long as possible (European Commission 2015; Stahel 2016). The circular economy, therefore, means reducing waste during production, ensuring asset recovery including waste utilization, and developing obsolescence prevention pathways in product and urban system designs through sustainable materials management (**Box 17.5**). It also means ensuring product and

service delivery with energy and materials from renewable sources, while changing business models to match these objectives (Ghisellini, Cialani and Ulgiati 2015; Rizos, Tuokko and Behrens 2017).

The circular economy preserves raw materials, thereby decoupling economic growth from the use of resources and its associated environmental externalities, including carbon emissions. However, in some cases the appearance of growth decoupling in one sector or territory can mask a continued environmental and social impact somewhere else (details in Ward *et al.* 2017). Ward *et al.* (2017) cite substituting one non-renewable resource for another (e.g. the cleaner energy systems that replace fossil fuels still require non-renewable resources) and shifting the cost somewhere else (e.g. importing resource-intensive consumer goods from developing countries).

#### 17.6.2 What are the elements of the system that the policies seek to address?

Policies that support the transition to circularity are being developed and implemented in many places and involve a range of different approaches. Early examples include the German Closed Substance Cycle and Waste Management Act introduced in 1996 to recover materials from municipal and production waste (Germany, Federal Ministry for the Environment, Nature Conservation and Nuclear Safety [BMU] 2011) and the Japanese recycling initiative Basic Law for Establishing a Recycling-Based Society (Environment Agency Japan 2000). These actions are examples of what has become known as the 3Rs of reduce, reuse and recycle, and are the foundation of green manufacturing and consumption (Jawahir and Bradley 2016). However, in the last decade the focus has expanded from 'green' to sustainable manufacturing – for example, the 6Rs of manufacturing, which in addition to reduce, reuse and recycle, include recover (for a subsequent life cycle), redesign (the next generation of products) and remanufacture (meaning restoration to an 'as new' form) (Jawahir and Bradley 2016; **Figure 17.5**).

#### Box 17.5: Sustainable materials management

Sustainable materials management (SMM) is a policy approach that expands the focus of waste management to the whole life cycle of a material – from extraction to end of life. It seeks to maintain the availability of products and services by conserving valuable resources and keeping them in circulation indefinitely. One of the key aims of the holistic management approach is to reduce impacts on the environment across the whole life cycle of a resource. Producers and manufacturers need to extend sustainability across the value chain – this involves ensuring the sustainability standards of all suppliers, integrating sustainability into the design process, and identifying and addressing any negative social and environmental impacts.

Reducing the volume of waste produced and increasing material recovery are essential components of SMM (United States Environmental Protection Agency [US EPA] 2015). SMM promotes resource efficiency, which includes minimizing the economic, environmental and social costs of a production process and resource productivity, defined as the effectiveness with which natural resources are used (OECD 2012).

**Figure 17.5: Closed-loop material flow diagram of 6R elements and the four life cycle stages**

Source: Jawahir and Bradley (2016).

**Table 17.3: Examples of policy focus to achieve key elements of the circular economy**

| Key elements of the circular economy             | Policy examples                                                                                                                                                                                                                                                                                                                                                                                                                             | Result examples                                                                                                                                                                                                                                                                                                                                                                         |
|--------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Design for the future</b>                     | EU Ecodesign Directive – ensures energy efficiency of products, such as household appliances, by setting minimum efficiency requirements (EU 2009).                                                                                                                                                                                                                                                                                         | It is estimated that the Ecodesign Directive will deliver a 16 per cent reduction in the primary energy consumption of 35 product groups compared with the consumption of these products in 2010. For example, the energy efficiency of televisions, under the Ecodesign scenario it is predicted to improve by a factor of 25 (measured from 1990) by 2030 (European Commission 2017). |
| <b>Market-based instruments – green taxation</b> | Taxes on virgin materials such as sand, gravel and rock used in the construction industry have been introduced by 16 EU states.                                                                                                                                                                                                                                                                                                             | The United Kingdom of Great Britain and Northern Ireland introduced a tax on aggregates in 2002. Since the introduction of the tax, primary aggregates use has reduced by approximately 40 per cent per unit of construction (Ettlinger 2017).                                                                                                                                          |
| <b>Incorporate digital technology</b>            | Republic of Korea has some of the world's fastest internet speeds, with connections to more than 90 per cent of the population. The government has provided economic support for broadband infrastructure development, subsidies to ensure connectivity, and measures to stimulate information technology literacy (Falch and Henten 2018).                                                                                                 | Streaming music reduces resource use and costs 80 per cent less than the cost of producing and distributing of compact disks (CDs) (Lacy 2015). The Republic of Korea was the sixth top music market in 2017 and has the largest number of paid music subscribers (International Federation of Phonographic Industry [IFPI] 2018).                                                      |
| <b>Collaborate</b>                               | In Sydney, Australia, the city council introduced policies to promote car sharing, including the provision of designated car-share parking spaces; and online listing of private vehicles participating in peer-to-peer sharing schemes (City of Sydney 2016).                                                                                                                                                                              | GoGet is an Australian car-sharing company, operating in large cities. Members have access to a range of vehicles including cars and vans (GoGet <a href="https://www.goget.com.au">https://www.goget.com.au</a> ).                                                                                                                                                                     |
| <b>Use waste as a resource</b>                   | In 1997, Denmark introduced legislation that banned sending waste that could be recycled or incinerated to landfill. In 2015, a new law was introduced, the Environmental Technology Development and Demonstration Programme (MUDP). This includes a subsidy scheme, innovation partnerships and international cooperation to find resource-efficient solutions to environmental problems (Denmark, Ministry of Environment and Food n.d.). | The Kalundborg Symbiosis in Denmark is a network of businesses that was the first industry group to fully develop industrial symbiosis. The collaboration includes a coal-fired power plant, fish farming, fertilizer production and a host of other manufacturing and industrial operations (Kalundborg Symbiosis 2018).                                                               |
| <b>Rethink the business model</b>                | New business models that utilize technologies are emerging, such as blockchain. Estonia, for example, has established an e-residency scheme to encourage entrepreneurs. E-residency provides anyone with a digital ID that allows them to access Estonia's e-services for online business development and management from anywhere in the world.                                                                                            | The China Construction Bank Corporation (CCB) is using the IBM Blockchain platform to improve procedures for the sale of its insurance products.                                                                                                                                                                                                                                        |
| <b>Preserve and extend existing products</b>     | The right to repair – the EU is preparing legislation making it mandatory for companies to provide spare parts and diagnostic tools that would make it cheaper and easier to repair products (European Parliament, Committee on the Internal Market and Consumer Protection 2017)                                                                                                                                                           | Inrego, a Swedish firm, is refurbishing electronic equipment such as laptops, personal computers, monitors and phones (European Remanufacturing Network 2018).                                                                                                                                                                                                                          |
| <b>Prioritize regenerative resources</b>         | Norwegian policies to support battery electric vehicles (BEV): zero annual road tax (2018); 40 per cent reduced company car tax (2018); 50 per cent price reduction on ferries (2018); zero re-registration tax for used zero-emission cars (2018); free municipal parking in many cities (Norsk elbilforening 2018).                                                                                                                       | In Norway, incentive programmes to encourage use of BEVs began in the early 1990s. Norway currently leads the world with 21 per cent BEV market share (cf. Australia, where there is limited incentive and BEVs have 0.2 per cent of the market (ClimateWorks Australia 2018).                                                                                                          |

China adopted the circular economy as a development strategy in 2002, and this was given legal effect in 2009 through the Circular Economy Promotion Law (China, National People's Congress 2008). The European Commission released a 'Roadmap to a Resource Efficient Europe' in 2011, which was

replaced in 2015 by 'Closing the Loop: An EU Action Plan for the Circular Economy' (McDowall *et al.* 2017). Both Europe and China were following earlier research and policy work in the United States of America, Japan and Europe that focused on waste management.

### Box 17.6: Case study: Ellen MacArthur Foundation – A toolkit for policymakers in delivering the circular economy

The Ellen MacArthur Foundation, a UK-based non-governmental organization, has been a leading proponent of the circular economy, funding extensive research and education programmes. In 2015, the foundation partnered with the Danish Business Authority to develop a toolkit for policymakers (Ellen MacArthur Foundation 2015). In the development of the toolkit and subsequent pilot studies, the authors identified seven key insights which provide evidence of the potential economic, environmental and social benefits of moving towards a circular economy.

- ❖ A circular economy fosters more innovation, resilience and productivity, resulting in increased gross domestic product (GDP) and jobs, and reduces greenhouse gas emissions and virgin non-renewable resource consumption.
- ❖ Policymakers can break down the non-financial barriers that challenge the circular economy.
- ❖ There is no overarching solution that will instigate a circular economy – each sector must be analysed and tailored policies should be instituted.
- ❖ An overhaul of financial systems and the way we measure economic performance (i.e. currently excluding externalities such as environmental damage or social dislocation) will help illuminate the real value in transitioning towards a circular economy and the real cost of business as usual.
- ❖ Business needs to lead the way in identifying circular economy opportunities.
- ❖ Even developed countries that are moving towards a circular economy can increase the rate of change by scaling up and fostering enabling conditions across all sectors.

There needs to be policy coordination across countries as value chains extend across borders.

The policy environment is expanding, with states and other stakeholders such as the Ellen MacArthur Foundation playing an important role in promoting the circular economy transition to business and industry (see Figure 17.6).

Figure 17.6: Outline of a circular economy

Source: Adapted from Circular Norway (n.d).

### 17.6.3 What has been done to date and how effective have these measures been?

Many governments have introduced policies and regulations that address aspects of the circular economy. Policies supporting the circular economy can focus on one or more elements of the 'take, make and waste' process. While many policies have tended to address waste through recycling and resource recovery, there are significant gains to be made at the earliest stages of product design and manufacture. For example, products can be designed using eco-design principles, to use less material and last longer. They can be refurbished or repaired and made of non-toxic materials that are simple to recycle.

Policies that encourage eco-design also need to consider the potential adverse health, gender and developmental impacts of poorly planned policies (e.g. toxic exposures for women and children from recycling electronic waste). About 15 million people are involved in informal waste recycling of plastics, glass, metals and paper where these activities are a risk both to the environment and to the people performing the tasks (Yang *et al.* 2018). Individuals performing resource recovery, especially e-waste pickers in developing countries, risk considerable occupational and environmental health threats (Velis 2017). Women and children are among the vulnerable groups working in this informal sector who face exposure to hazardous chemicals and heavy metals (Heacock *et al.* 2016), with few to no measures for prevention or treatment (Han *et al.* 2018).

Policies can also support the move from managing waste to more environmentally sustainable outcomes, by focusing on behaviour change. These policies, which are often developed from grass-roots initiatives, aim to limit the amount of waste produced and increase material recovery (Silva *et al.* 2017).

Europe has established policies for implementing the circular economy, while in other areas this has happened at a national or subnational level. There have also been some international policy initiatives that align with, or promote, a circular economy approach, especially with regard to waste minimization (e.g. the Basel and Stockholm conventions). The new approach of green (or sustainable) chemistry is working to develop alternative solutions aimed at eliminating or at least significantly reducing hazardous chemicals and eventually their presence in the environment (Weber, Lissner and Fantke 2016). One of the

challenges in relation to chemicals and the circular economy is increasing recycling and reuse, while making sure consumers are not at risk from exposure to substances of concern that may be present in products and passed on through waste (European Commission 2015). For some chemicals and toxic metals, such as persistent organic pollutants (POPs) and mercury, final disposal may be a better option than recycling and reuse.

### 17.6.4 What is the transformative potential of the policy approaches discussed?

A transition to a circular economy will be required in order to achieve the SDGs. There are insufficient natural resources to sustain the continued expansion of a global economy based upon a linear economic model. The circular economy offers opportunities not only to address fundamental resource constraints but also to create a more just and inclusive economic system (Raworth 2012). Circular economy policies therefore carry major transformative potential to address cross-cutting policy challenges.

### 17.6.5 Indicators

No indicator provides a single measure of progress towards a circular economy. However, there are several existing indicators of performance in areas that directly or indirectly contribute to the achievement of a circular economic system. Sustainable resource management, societal behaviour, business operations, material flow accounting or analysis are among a number of measures that have been proposed (Geng *et al.* 2012; Wiedmann *et al.* 2015; United Nations Environment Programme [UNEP] 2016). Taking into consideration linkages with the SDGs, we identify two policy-relevant indicators of circularity.

#### **Indicator 1: Domestic material consumption (DMC) (SDG indicators 8.4.1, 8.4.2 and 12.2.2)**

Domestic material consumption measures the territorial consumption of primary materials used in the economy, whether these are domestically sourced or imported. This indicator allows a comparison to be drawn between regions and states in per capita material consumption over time. DMC can also be used to estimate the amount of waste that may be generated in a given region. Domestic extraction (DE) is the amount of materials extracted in a given territory. DMC is higher than DE in net material importing countries and lower than DE in net material-exporting countries (**Figure 17.7**).

Figure 17.7: Domestic extraction and Domestic material consumption

The figure shows data on extraction, trade, and apparent consumption of materials for six regions in Gigatonnes per year (Gt/a) and in per capita values per year (t/cap/a). DE: domestic extraction; DMC: domestic material consumption.

Source: Schaffartzik *et al.* (2014).

## Indicator 2: Societal behaviour (SDG indicators 12.2.1 and 12.2.2)

In addition, developing a circular economy will involve people changing their consumption behaviour and choosing products and services that conserve resources. Sharing resources, a common strategy in many subsistence economies, is being increasingly adopted around the world. Sharing of expensive or infrequently used products such as cars, bikes, holiday houses, camping and other recreation equipment may be organized as formal schemes or informal agreements within communities (Figure 17.8).

## 17.7 Conclusions

The cross-cutting nature of sustainability issues is well illustrated by the interactions across SDGs (Nilsson, Griggs and Visbeck 2016; Biermann, Kanie and Kim 2017; International Council for Science 2017). Meeting one goal or target will not guarantee that other SDGs will be achieved, just as some Millennium Development Goals (MDGs) were achieved in some parts of the world but not in others (Boas, Biermann and Kanie 2016; Kim 2016; Underdal and Kim 2017; Young 2017). This lesson is not new, but the overdue shift towards systemic policy approaches is beginning to occur. Some go as far as to argue that “the single most important [environmental] problem is our misguided focus on identifying the single most important problem” (Diamond 2005). The systems approach to environmental policy development and implementation, discussed in this chapter, can address multiple global goals

and is no longer an option but is the only way forward for societal transformation to achieve global sustainability.

This chapter highlights the complex linkages between sustainability issues and the ways in which these present both challenges and opportunities. They are challenges in the sense that cross-cutting issues are difficult to address individually through incremental steps and in isolation from one another. As concluded in the thematic chapters of Part B (Chapters 12–16), many well-intended environmental policies and measures have had limited success. Policy improvements are visible, but they have not been made at a sufficient rate or scale. New sustainability issues have emerged that have greater complexity, often due to the unanticipated ways through which existing issues have interacted with one another. Some of the unwanted outcomes of interaction between global drivers in turn act as drivers for further suboptimal outcomes (Walker *et al.* 2009).

As the analyses in this chapter have shown, however, systems policy approaches with transformative potential do exist. If key leverage points can be identified in a system and the right policy interventions are made (Meadows 2008), transformative change leading to innovations will lead to net positive effects. Even small-scale interventions can sow the seeds for the larger systemic change that is required to deliver the SDGs. This chapter chose four socioeconomic systems to illustrate the transformative potential of the systemic approach to environmental policy intervention.

**Figure 17.8: Citizen engagement in sharing: the percentage of 2013 survey respondents who had engaged in a sharing scheme, either formal or informal in the previous 12 months**

Source: Flash Eurobarometer 388 (2013)

Environmental, social and economic systems need to be understood and analysed by appreciating their complexity. Some understanding of a system is a prerequisite to identifying leverage points, that is, where 'seeds can be sown'. Acknowledging that there is no policy panacea (Ostrom 2007), various clusters of policies can then be deployed, and some degree of redundancy can be helpful as a policy safety net (Low *et al.* 2003). It is very difficult to predict whether a policy will work effectively to solve a cross-cutting issue without producing significantly perverse and unintended consequences. Attention to one element of a cross-cutting issue can lead to environmental problem shifting – both transboundary and trans-sectoral, or trade-offs and

spillovers (Kim and van Asselt 2016). Adaptive governance or management approaches are therefore required that use experimentation (Hoffmann 2011) to build on lessons learned rather than 'reinventing the wheel'.

An effective response to cross-cutting environmental policy challenges requires cooperation and collaboration among a multitude of actors and institutions across issues, sectors, levels and jurisdictions. The transformation pathway for achieving human dignity and environmental sustainability this century requires a whole-of-system approach that can catalyse rapid technological innovation and economic and cultural paradigm shifts.

# Chapter 18

## Conclusions on Policy Effectiveness

**Coordinating Lead Authors:** Klaus Jacob (Freie Universität Berlin), Peter King (Institute for Global Environmental Strategies), Diana Mangalagiu (University of Oxford and Neoma Business School)

**Contributing Author:** Beatriz Rodríguez-Labajos (Universitat Autònoma de Barcelona)

## 18.1 Overview of the outcomes

This chapter presents a set of conclusions for Part B of the sixth Global Environment Outlook (GEO-6), reached through the findings of the previous chapters about policy effectiveness (Chapters 10-17). It summarizes for policymakers what is known to work best and why, including a synthesized discussion of the limitations of the evidence available to date for policy effectiveness. We also make reference to Part C (Outlooks), which will examine the promising emerging policies for the future.

There is considerable innovation in policy approaches and instruments across all the environmental themes covered by the sixth Global Environment Outlook (GEO-6) (Chapters 12-17). New institutions, policies and policy instruments have been developed and introduced all over the world. Environmental policy innovation takes place not only in Western industrialized countries, but also in emerging and developing economies. Policies are developed that go beyond technical fixes by increasingly addressing social and economic practices.

Environmental policy innovation also takes place to address issues of equity and environmental protection at the same time. Examples of this include the territorial rights for fishing in Chile, or the free basic water allocation in South Africa, both of which are measures to secure access to natural resources for low-income communities while at the same time promoting sustainable management.

Environmental policies aim to reduce emissions and depletion of resources by encouraging behavioural change or limiting the choices of consumers, enterprises and communities. Different modes of intervention are being used: persuasion, economic incentives and regulation.

There is no single instrument for complex environmental problems, and policy mixes are more effective, often combining different modes of governance that mutually reinforce each other (referred to as 'hybrid governance'). Combining measures on the demand side, for taxing and labelling environmentally harmful consumption, with measures on the production side, to limit emissions, is one example that can mutually reinforce environmental innovation, and create markets for it.

Environmental policies are also defining the processes that enable and encourage actors to reflect on their environmental performance – environmental impact assessments, planning procedures and environmental management systems, for example.

Chapters 12-17 also show that environmental actors within and beyond governments are being established or strengthened by many environmental policies, showing an unfolding of effects on environmental performance. Environmental policies and institutions do not determine resource use and emissions on their own – there is also the role of policies in sectors such as housing, infrastructure, agriculture, industry, energy, and so on. A further mechanism that promotes effective environmental policy – albeit a difficult one to achieve – lies in the integration of environmental concerns into other sectoral policies.

While policy integration promises to settle conflicts between environmental and other objectives (Nilsson *et al.* 2012; Runhaar, Driessen and Uittenbroek 2014; Mullally and Dunphy 2015), the analysis in the previous chapters demonstrates that this has rarely been achieved in practice. There is a lack of systematic evidence on how sectors such as agriculture, transport, urban planning and water management can incorporate environmental standards to prevent, reduce or mitigate harmful environmental effects. Changes in policy mixes are often compelled by pressure from different groups and sectors that have opposing stakes on a resource, environmental asset or ecosystem service.

Many countries (and some international organizations) have begun to adopt integrated approaches or instruments to assess the potential impacts of proposed legislation on stakeholders and their well-being, economic sectors, and the environment (Radaelli 2009; Jacob *et al.* 2011; Adelle and Weiland 2012; Adelle *et al.* 2016; European Environment Agency [EEA] 2017). Such integrated policies may help to achieve the broader set of Sustainable Development Goals (SDGs) in a cost-efficient way, overcoming existing barriers and trade-offs.

Environmental policy integration tools include regulatory impact assessment, environmental and health impact assessment, and strategic environmental assessment. These evidence-based policymaking tools are increasingly being adopted to demonstrate the need for improved environmental policies. Considerable experience is emerging in the use of these tools, particularly in the European Union.

To date, however, there is little evidence to measure the level of policy integration or the actual outcomes from applying various tools. Among the few exceptions is the Partnership for European Environmental Research (Mickwitz *et al.* 2009), which assessed climate policy integration in Europe, at multiple scales. A key lesson from the project is that cities and municipalities have begun to integrate climate aims into their strategies and plans, and that such authorities sometimes have more ambitious goals than national governments.

An important argument in favour of environmental policy integration is the expected economic and social co-benefits from implementing environmental policies. These co-benefits include additional economic growth spurred by innovation, savings from the conservation of natural resources, and the avoided costs of environmental damage. The United Nations Environment Programme (UNEP) estimates that two per cent of global gross domestic product (GDP) in green investment would deliver long-term economic growth while minimizing the adverse impacts of climate change, water scarcity and loss of ecosystem services (UNEP 2011).

The analysis in GEO-6 of environmental policies and their integration demonstrates the diversity of institutional and cultural frameworks in which policymaking takes place. The roles of law, values, administrative capacities, socioeconomic conditions, and so on, are important in how effective policies can be. The design of policies that reflect on this set of conditions is important.

The effectiveness of the thousands of policy innovations cannot be assessed comprehensively; a case-by-case approach is needed to make evaluations. The effectiveness of different policy instruments cannot be compared given the multiple market failures, including, among others, the lack of price signals, lack of information and network effects. There is no evidence, for example, to support claims of a general superiority of market-based instruments over regulatory or persuasive ones. The analysis presented here by GEO-6 does show evidence, however, for the need to combine different policies into complementary policy mixes of clusters. Despite the recognition that coherent policy mixes are often more effective than stand-alone policies, the interplay of instruments within mixes is not well understood, aside from the rather broad understanding that some policy instrument types do not necessarily work well with others.

Effective and ambitious environmental policies are often contested by the sectors affected. Their design, and the level of ambition, is usually the subject of negotiation in the policy process, during which environmental actors usually need to find compromise. Second-best environmental policies are often adopted as a result. For many issues and in many countries, environmental policy does not make use of potentially powerful mixes of price signalling and hard regulation. Instead, mechanisms of persuasion, self-regulation or subsidy are introduced. Chapters 12-17 also find, finally, that vested rights and interests are often not touched on, with environmental policies instead focusing on new products or sites, by having permitting procedures for development projects, for example.

Once environmental policies have been established successfully, their scaling up has been observed. Moreover, new opportunities and capacities for advancing policies, and for raising the level of ambition over time have been observed once the technical, social and economic feasibility has been demonstrated and markets for environmentally friendly alternatives have been created. In a few cases, these opportunities were built into the policy design from the very beginning. The commitment for a continuous improvement of policies over time could be applied much more often than it is today, in the manner of the so-called ratchet mechanism of the Paris Agreement on climate change (United Nations Framework Convention on Climate Change [UNFCCC] 2015).

In view of the challenges outlined above, there is an emerging consensus that the design of policy instruments is at least as important as the choice of the instrument, for the effectiveness of individual policies and policy mixes (Yin and Powers 2010; Flanagan, Uyarra and Laranja 2011; Kemp and Pontoglio 2011). The temporal dynamics of policy change, how and why specific policies stick (or fail to stick) and how policy choices interact in an increasingly complex policy mix all need to be better understood. As these lessons are learned over time, the level of ambition is expected to increase – especially, as the GEO-6 finds, if environmental policies prove to have economic and social co-benefits.

Added to the observation that environmental policies are being scaled up within national borders, they are also diffusing across jurisdictions. Other countries, regions or communities are taking up and adapting the examples of pioneering countries. Some publicly available data sets aim to facilitate the charting of this diffusion, particularly for policies on climate

change and renewable energy. The Climate Change Laws of the World database from the London School of Economics (Grantham Research Institute on Climate Change and the Environment 2017), for example, compiles information on national-level climate policies ranging from transport policy to adaptation and mitigation. Similarly, REN21's Global Status Report (Renewable Energy Policy Network for the 21<sup>st</sup> Century [REN21] 2018) charts the use of renewable energy policies across a large sample of national and subnational jurisdictions. InforMEA, finally, is the United Nation's portal for information on multilateral environmental agreements (UNEP, Food and Agriculture Organization of the United Nations [FAO] and United Nations Educational, Scientific and Cultural Organization [UNESCO] 2018).

Despite the prolonged interest in the spatial diffusion of environmental policies, and efforts to provide systematic policy information on it, knowledge about this particular aspect of policy development remains limited, especially outside the specific policy field of renewable energy. There is also a lack of research on the role of local contexts on the effectiveness of policies adopted from abroad. There is some evidence that less ambitious policies (e.g. distributional rather than re-distributional policies) are the subject of policy diffusion more often than cross-jurisdictional policies. This is in spite of the fact that policy diffusion may be considered a positive mechanism for learning across different jurisdictions – often facilitated by international regimes and multilevel governance.

The GEO-6 analysis finds that the importance of good policy design for the effectiveness of environmental policies cannot be overstressed. Mickwitz *et al.* (2009, p. 12) list some common elements of good design:

- ❖ set a long-term vision and avoid crisis-mode policy decisions, through inclusive, participatory design processes;
- ❖ establish a baseline, quantified targets and milestones;
- ❖ conduct *ex ante* (before implementation) and *ex post* (after implementation) analyses of cost-benefit or cost-effectiveness to ensure the best use of public funds;
- ❖ build in monitoring regimes during implementation, preferably involving affected stakeholders; and
- ❖ evaluate the policy outcomes and impacts, to close the loop for improving future policy design.

Despite this comprehensive list, assessments of policy effectiveness both *ex ante* and *ex post* against a baseline are usually missing, even for well-designed policies. The analysis finds that policy evaluation tools are rarely used. An evidence base for measuring policy effectiveness is therefore lacking because it is difficult in many cases to attribute effects to environmental policies, and whether these effects would have taken place without the policies. Impact assessments and policy evaluations are not being applied in a systematic way. Therefore, while the analysis of indicators, and the distance still to go to reach the goals, suggests that environmental policies are not yet sufficiently effective to achieve sustainable development, the analysis cannot reveal which policies and policy instruments are more effective or efficient than others.

There is no universally accepted methodology that can show causal relationships between the effects and the policies adopted, and unequivocal answers on policy effectiveness

Unfortunately cannot be provided. It is rarely feasible or ethical in the environmental domain to conduct policy experiments that show the counterfactual – that is, what would have happened had there been no policy?

Further, the literature shows the importance of various constraining and enabling factors, such as institutional capacity and political will. Policies also rarely stand alone, and the importance is stressed, as discussed earlier, of coherent, synergistic policies, or policy mixes. It is important, too, to recognize co-benefits and unintended side effects. Finally, spillover effects need to be recognized, especially where these involve transboundary concerns.

Accordingly, a two-track process was adopted for the assessment of policy effectiveness (Chapter 10) in GEO-6. For the top-down perspective, the author teams identified typical policy approaches that have been employed to solve key environmental problems in the areas of air, biodiversity, oceans, land, fresh water (surface and groundwater), and cross-cutting issues (Chapters 12-17). To illustrate experience in the implementation of these policy approaches in greater detail, specific case studies were selected, and effectiveness criteria derived from the literature were used to provide a qualitative assessment of policy effectiveness.

The second track, bottom-up, was to identify policy-sensitive indicators, meaning that one should be able to construct, again from the literature, a plausible story around why each indicator appears to be improving in response to a policy or policy mix. Within Chapters 12-17, the subsections on indicators therefore cover:

- ❖ their descriptions and their relation to SDGs or other multilateral environmental agreements;
- ❖ how data are collected for each indicator;
- ❖ a plausible line of argument for how an observed improvement in the indicator across multiple countries could be due, at least partly, to one or more policies;
- ❖ what other factors might explain the improvement; and
- ❖ what alternative indicators could verify the role of policies.

The narrative is interspersed with infographics. Depending on the availability of data in the literature, these help to show: correlations between the adoption of certain policies by countries and improvements in the indicators; trend analysis showing improvement in the indicator; or the numbers of countries reporting on the indicator over time.

From the limited number of case studies that could be addressed in GEO-6, it is apparent that there are very few cases where all the effectiveness criteria have been comprehensively covered at the policy design, implementation or post-evaluation stages of the policy cycle. In many cases, no quantifiable baseline was established, making it difficult to show quantitative evidence that the policy was improving environmental outcomes as intended. In most cases, there was no *ex ante* cost-benefit or cost-effectiveness analysis, making it uncertain that the best policy choice had been made. While co-benefits were often identified, in most cases through hindsight, there was no evidence of a deliberate, prospective attempt to ensure policy coherence and synergies. While most policies specifying a timeframe had been conducted within that period,

a surprising number of case studies appeared to be open ended, with no specific time for closure, evaluation or renewal. Many of the case studies were linked to global processes and agreements, which suggests that comprehensive environmental agreements like the Paris Agreement and the SDGs do provide an overarching policy framework that guides national policy processes.

The findings from GEO-6's assessment of policy effectiveness, as well as from its assessment of the evaluation methods used, have the potential to help develop a baseline for future research and global assessments. Continued efforts on policy evaluation would also help to close these gaps in data.

## 18.2 Connections to future policy

The analysis above of policy effectiveness inevitably comes after a lag in time because policymakers do not know if a policy has been effective until some years after its initial implementation, especially if part of the indication of effectiveness is viewed to be implementation across multiple countries. This means that Part B has not been able to showcase new emerging, promising policy approaches, which are instead addressed in Chapter 24 (The Way Forward). Future editions of GEO will need to assess the eventual effectiveness of these policy approaches following their implementation. Policymakers have the opportunity meanwhile to examine the effectiveness criteria selected in GEO-6 and to use these when designing the new generation of policies and planning their evaluation.

Improved policies and governance arrangements will form an essential part of crafting pathways towards sustainability. It is likely that the emerging and promising policies covered in Part C (Outlooks) will come into this picture – because the current set of policy approaches are unlikely, with the required urgency, to achieve the SDGs, Paris Agreement and other multilateral environmental agreements. One example of the need for new innovative policy is that the setting of national standards, as part of the normal command-and-control policy approach to combating pollution, is too slow and unwieldy to keep up with the thousands of new chemicals, materials, genetically modified organisms and nanotechnologies being released into the environment every day.

## 18.3 Gaps in knowledge

The policy-effectiveness analysis conducted for GEO-6 has struck out into a new direction for UN Environment. Policymakers want to know which policies work and why, but assessments should not stray too far into policy advocacy. The costs of inaction and inordinate delays in policy implementation also need to be studied, as well as the effectiveness of policy action. The key gap, surprising many of the authors, was the paucity of well-documented evaluations of the selected case studies that illustrate the importance of the science-policy interface. It appears that in most countries it is either not the practice to conduct post-evaluations of policies, or if such evaluations are conducted then the results are not in the public domain.

We suggest that UN Environment works with member countries to extract those policy evaluations not currently in the public domain to create a section for policy effectiveness in the online data portal, Environment Live. Researchers and

policy think tanks should also be encouraged to conduct policy-effectiveness studies to provide the independent analysis that appears to be in short supply.

The need for a universally acceptable methodology to assess policy effectiveness represents another critical gap. The challenge for researchers and policy think tanks is to conduct such analyses regularly, and for policymakers to apply this information in advancing policymaking.

Another gap in knowledge relates to the policy-sensitivity of indicators. Among the hundreds of indicators selected for the SDGs, which of these are policy-sensitive? Of the indicators that are policy-sensitive, what are the corresponding policies that they are sensitive to? Which of these should governments be considering to achieve accelerated progress on the indicators? Of the SDG targets that UN Environment is responsible for, which are policy-sensitive, and what should be the role of UN Environment in not only tracking these but also analysing policy effectiveness?

Finally, there is also a gap in relation to the analysis of social and economic policies, such as sectoral policies, that have important effects on environmental conditions. It is not sufficient to analyse only environmental policies. Tools such as Environmental Impact Assessments (EIA) and Strategic Environmental Assessments (SEA) can be used to examine the environmental consequences of projects, policies, plans and programmes. More importantly, however, sectoral agencies should engage with environmental experts for help with avoiding adverse environmental consequences to planned activities.

## 18.4 Key lessons from the analysis

**Consider policy effectiveness at the design stage.** Most of the weaknesses identified in environmental policy approaches stem from inadequate analysis at the design stage. The empirical analysis in GEO-6 demonstrates that, too often, environmental policy decisions are knee-jerk reactions to environmental crises rather than part of a deliberative, long-term process of policy selection and design to avoid environmental damage.

**Establish a verifiable, quantitative baseline.** A quantitative baseline that is science-based and verifiable, with firm targets, is an essential component of effective policies. For policies that will take a long time to reach fruition, quantitative milestones will also help to ensure that policy implementation is on the right track.

**Conduct cost-benefit or cost-effectiveness analysis at the policy design stage.** For most environmental problems there are multiple alternative policies that could achieve the desired outcomes. Water pollution, for example, could be controlled by regulations to change production processes, by the establishment of ambient or discharge standards, by imposing discharge fees, or through dilution from upstream reservoirs – or some combination of these. An examination needs to be made at the policy-design stage on what is the most effective use of public and private funding. This needs to be checked

subsequently to ensure that the right policy choice has been made.

**Ensure policy coherence and synergy.** There is strength in numbers. Generally, a single, stand-alone policy will not be as effective as a mix of policies that work together towards the same policy goal. Equally important, however, is to examine policies that might adversely impact or conflict with the policy objective. For example, policies to promote renewable energy may be undermined by continued subsidies to thermal power plants.

**Conduct independent post-evaluation studies.** The literature examined for this report found that there were few independent post-evaluation studies of policies. Evaluation by governments is necessary and important, but greater confidence may be achieved by unbiased, independent studies. A crucial role for funding agencies, therefore, is to provide the necessary resources for more of these, particularly in developing countries, where there is a dearth of good policy assessment.

**Engage key actors in all aspects of the policy cycle.** A complex web of stakeholders who need to be involved in each part of the policy cycle is revealed by the case studies. This implies a need for transparency in the policy process. Inclusive policy processes will generally be more effective than those which exclude some of the actors. There may be a cost and additional time constraint in being inclusive, but this tends to be compensated during implementation, whereas protests or legal challenges could delay implementation plans.

**Identify the indicators that are policy-sensitive and can demonstrate causal links.** Establish a clear linkage from the indicators in the SDGs and other multilateral environmental agreements to known effective policies. The case studies showed the importance of multilateral agreements in the specific areas of air, biodiversity, oceans, land, fresh water (surface and groundwater), and in several cross-cutting areas. While such agreements are often unenforceable at the global level, they do carry moral suasion and provide peer pressure to embody the agreed approach in national and subnational policies, plans and programmes. Only weak links have been made so far between indicators and effective policy, however, and additional work needs to be done in establishing these connections.

**Conduct additional research on policy effectiveness.** Researchers often finish their assessments with a call for more research, but in this case, it is justified. There are remarkably few well-documented case studies of policy effectiveness that follow the policy decisions throughout the policy cycle, from design to post-evaluation. The future work of UN Environment needs to strengthen the link between policies and environmental outcomes, particularly since the indicators for SDGs are being monitored nationally and reported on globally. Further studies are needed on the political ecologies and stakeholder dynamics that underpin, drive or constrain the formation and movement of policies designed for environmental issues and sustainable development.

## Outlooks in GEO-6

**Coordinating Lead Author:** Ghassem R. Asrar (Pacific Northwest National Laboratory, United States of America)

**Lead Authors:** Paul Lucas (PBL Netherlands Environmental Assessment Agency), Detlef van Vuuren (PBL Netherlands Environmental Assessment Agency), Laura Pereira (Stellenbosch University Centre for Complex Systems in Transition), Joost Vervoort (Utrecht University)

**Contributing Author:** Rohan Bhargava (Utrecht University)

**GEO Fellow:** Semie Sama (Centre for International Governance Innovation)

## Executive summary

**For environmental assessments to be useful to decision makers, they should account for the interactions, interdependencies and co-evolutionary pathways of human-Earth systems in proposed policy options and scientific and technological solutions – including the direct effects and the co-benefits and/or trade-offs.** (*established, but incomplete*).

Global Environmental Assessments generally rely on model-based quantitative scenarios. While these models capture many important linkages, the social dimension is not very well represented. Moreover, it is difficult in global assessments to capture important details that are pertinent for local-level decision-making. A systemic and integrated approach is needed in scientifically based environmental assessments and future outlooks, in support of policy and investment decisions, to account for the highly complex, interdependent and continuously changing factors in assessing the human-Earth system changes {19.1}.

**Global assessments have to shift the focus from what is happening and what could be done, to how trends and trajectories in development can be changed** (*well established*).

The use of top-down and bottom-up methods in Part C of GEO-6 – Outlooks and Pathways to a Healthy Planet for Healthy People is intended to provide science-based information for this purpose. The combined quantitative scenarios and participatory approaches also offer great potential to be more responsive to meeting the sector- and region-specific information required by decision makers. Therefore, the GEO-6 outlook analysis/assessment use: (1) model-based scenario analysis (generally referred to as the top-down approach); (2) information and knowledge from past and present initiatives, opportunities and trends (i.e. seeds of change); and (3) information resulting from integrative decision-making and participatory activities that are usually conducted at the local to regional levels (generally referred to as bottom-up approaches). This will ensure greater engagement of stakeholders in knowledge development and dissemination, and implementation of resulting policies and practices in a timely manner for greater success {19.2, 19.3}.

## 19.1 Introduction

Parts A and B of the sixth Global Environmental Outlook (GEO-6) indicate that the current global development trends and their future trajectories are not sustainable. At the same time, nations worldwide have agreed on a set of ambitious goals as part of the United Nations 2030 Agenda for Sustainable Development, including the Sustainable Development Goals (SDGs), a broad range of multilateral environmental agreements and other frameworks. Together, they aim for halting environmental degradation and aim to enable better development pathways that can benefit both humans and the ecosystems that support human well-being.

The key questions now are whether future trends would lead to the achievement of these ambitious goals and thereby a more sustainable future – and, if not, what would be required, both in policy and practice, to bend the trend towards positive and sustainable development pathways. Part C of GEO-6 aims to provide an integrated and holistic view of the scientific information to address these questions. It presents new approaches to developing science-based information for decision makers, by combining scenario-based quantitative projections (defined here as top-down approaches) with grass-roots and participatory methods (bottom-up) approaches.

## 19.2 Important elements of future-oriented environmental outlooks

Changes in Earth-human systems, and their cascading effects, transcend a wide range of scales of space (i.e. local, national, regional, global) and time (seasons, years, decades and longer), and vary significantly in different sectors (agriculture and food, water resources, energy systems, fisheries, etc.). Such complexities need consideration, through the active engagement of stakeholders and decision makers, in the design, development and implementation of environmental assessments and outlooks. This is because of the interrelationships among, for example, the following:

- i. the choices for addressing legacy issues and current pressures (e.g. food-water-energy security),
- ii. the development of management approaches that are responsive to a changing environment (e.g. SDGs and other targets) and,
- iii. the extent to which emerging issues and future pressures are anticipated and prepared for.

Environmental assessments and outlooks should also consider the potential impact of proposed plans, policies and practices, and the need for improved communication between policymakers and the public. This requires consideration of the decision makers' needs much earlier in the assessment process. The expanding role of public, private and non-governmental organizations in the assessment process allows an intrinsic connection between environmental sustainability and equity, and enables the promotion of sustainability goals through this engagement (Simson 2012; Ho *et al.* 2013). The process of environmental assessment often has difficulty taking account of the socioeconomic impacts of development

activities and issues associated with, for example, biodiversity, human health and cultural norms. These were not usually taken into account in the past (Mahboubi, Parkes and Chan 2015; Reid and Mooney 2016; Kok *et al.* 2017). The effectiveness of environmental assessments should be evaluated against the ability to raise the level of the environmental values that are considered important by stakeholders, such as stewardship, services and socioeconomic factors (Arts *et al.* 2012). Furthermore, investigation of effectiveness should explore whether the assessment process and products have resulted in better decision-making and the achievement of the desired outcomes (Fischer and He 2009).

Recent agreement and frameworks – including the 2030 Agenda for Sustainable Development and the Paris Climate Agreement – recognize the need for a change in the current trends and direction, and the need to promote a systemic and integrated approach to assessing the highly complex, interdependent and continuously changing factors that underpin these trends, including the states and dynamics of human-Earth systems. To achieve goals related to biodiversity, for example, one also needs to take account of goals related to food production, water availability, climate change and air pollution. Decision makers can benefit from science-based assessments of the outlooks that include the direct effects, co-benefits and consequences of the available responses, to avoid unsustainable and risk-prone development pathways (Kowarsch *et al.* 2017). Thus, the emerging global architecture for sustainable development and its governance requires environmental outlooks to take into account the complexities and interlinkages of Earth-human systems for developing a diverse range of policies and pragmatic solutions.

The SDGs offer a framework for such a holistic approach to identifying innovative ways and means for advancing human well-being and health together with environmental stewardship (Dye 2018). This framework requires interdisciplinary as well as multidisciplinary scientific research and assessments to be the norm; for the urgency of short-term needs and actions to be balanced strategically with the long-term risks in resource planning and allocation; and for more collaborative and participatory approaches to be promoted, to engage governments, businesses and citizens to reconsider their roles, responsibilities and contributions to the implementation of multilateral environmental agreements (Simson 2012; Ho *et al.* 2013). Stakeholder engagement could, for example, be an integral part of business development to bring the three aspects of sustainability – environment, society and economy – to the heart of societal value creation.

Specifically, environmental assessments and outlooks should identify the transformative interventions needed to achieve sustainable development pathways towards the stated goals/targets (e.g. SDGs), to ensure a healthy planet for healthy people. Such transformations must consider the role of humans in the form of socioeconomic development, the roles of the perturbations of natural systems and built systems, such as infrastructure, and also the interactions and interplay among these roles.

### 19.3 A new framework for combining top-down and bottom-up analysis methods

Various methods have been developed over the past decades to conduct environmental assessments and outlooks in support of decision-making. Model-based scenario analysis, for example, has been used as a method to define plausible future conditions, in relation to the current state and trends in socioeconomics, technologies, environmental conditions and policies (van Vuuren *et al.* 2012). In this approach, an envisioned scenario is a plausible and often simplified description of how the future may take shape, based on a coherent and internally consistent set of assumptions about key driving forces and their relationships (Millennium Ecosystem Assessment 2005). As such, scenarios are powerful tools that can help to conceptualize how alternate futures might unfold. They provide insight on where alternative pathways for sustainable development might lead us by taking into account the many interrelations between different subsystems (e.g. energy, agriculture, cities, etc.) and societal concerns (health, economy, climate, air, freshwater, biodiversity, etc.), thereby specifically addressing synergies and trade-offs between different developments and aspirations. Given the inherent uncertainty about the future, scenarios and associated analyses are also helpful for both assessing the future implications of different problems and inspiring the narratives around which decisions are made (with due consideration given to the level of confidence in their certainty and their likelihood of success). This approach is also referred to as the top-down approach and it usually starts with the consideration of a given policy and traces the causal chains expected by its implementation (see Chapters 21 and 22). It offers the opportunity to evaluate the potential effectiveness of the policies under consideration by evaluating the quantitative representation of the various systems involved, the interlinkages between them as much as possible, and the creativity used to represent these complex systems, often based on the current state of knowledge about them.

In contrast, the increasingly prominent participatory approaches, also known as bottom-up approaches, begin from the observed outcomes and trace the causality back to the policy interventions (see Chapter 23). Most of these approaches are based on the active engagement of stakeholders and citizens through workshops, crowdsourcing and competitions to identify innovative ideas, practices and solutions. The identified needs being answered are often sector- and region-specific, resulting in an evolution in the diversity of participatory approaches over the past decades. The greatest advantages of bottom-up approaches are threefold:

- i. they focus on specific local and regional development challenges,
- ii. they engage stakeholders and users in planning the intended analysis, and in the resulting knowledge for its design, development and implementation, and,
- iii. they provide the ability to develop sector- and/or region-specific analysis and information.

The bottom-up approaches do have some limitations, such as their limited ability to be extended to larger scales, and their limited sustainability over time. They nonetheless offer significant potential considering the rapidly increasing needs for information for decision makers at local and subnational levels, and the desire to engage stakeholders actively in the knowledge-development process (Jabbour and Flachsland 2017; Kowarsch *et al.* 2017).

GEO-6 therefore uses both top-down and bottom-up approaches and methods towards target-seeking scenarios. This builds on the assessments in previous GEOs and pre-SDG pathways analysis and is based on quantitative scenarios (van Vuuren *et al.* 2015; see also Chapters 21 and 22) and on the participatory and grass-roots analysis that has been conducted through stakeholder workshops and crowdsourcing approaches (see Chapter 23). This opportunity to combine the desirable attributes of different approaches offers great potential for assessments and outlooks to capture the increased complexities of Earth-human systems and their interlinkages, and to be responsive to decision makers' needs for sector- and region-specific information. Some new features of the outlook analysis provided by GEO-6 are:

- ❖ A combination of top-down (e.g. pathways and trajectories) and bottom-up (or participatory) approaches (e.g. game changers, effective seeds and crowdsourcing) to ensure the efficacy and effectiveness of the resulting analysis.
- ❖ A focus on the 'how' question in integrated scenario analysis, by explicitly discussing target-seeking scenarios and linking them to the evolution of the pathway experience in the literature, with specific attention given to the synergies and trade-offs in simultaneously achieving well-being and environmental goals.
- ❖ The engagement of stakeholders in knowledge development, implementation and dissemination – through regional and sectoral stakeholder workshops and crowdsourcing platforms, for input into analysing, testing and refining the outcomes.
- ❖ Communication with decision makers (e.g. policy experts) throughout the knowledge-development process, not just in the final product, and using innovative means for communicating assessment outcomes, to increase their uptake in policy and practical decision-making.

The global top-down pathways considered in GEO-6 are based on a review of existing work, and can be grouped in three potential pathways that can drive change (PBL Netherlands Environmental Assessment Agency 2012; van Vuuren *et al.* 2012), namely:

- i. technological innovations, which can serve as the dominant reason for change,
- ii. shifts in consumer choices and behaviour, and,
- iii. decentralized innovation in favour of more localized and community-level activities.

The bottom-up approaches evaluated in GEO-6 capture the richness of practices, ideas and visions for desirable global futures using a variety of methods – examples include the Climate CoLab platform from the MIT Center for Collective Intelligence (Malone *et al.* 2017), initiatives dubbed the “seeds of a good Anthropocene” (Bennett *et al.* 2016), and the pathways projects sponsored by the European Commission’s Seventh Framework Programme (Kok *et al.* 2015; see Chapter 23). The combined approach offers the potential to develop the required science-based analysis for the successful implementation of the SDGs, together with that of other multilateral environmental agreements (European Commission 2016; Patterson *et al.* 2017).

## 19.4 The role of scale

Scales play a key role in environmental assessments (Gibson, Ostrom and Ahn 2000; Cash *et al.* 2006; Vervoort *et al.* 2012) because most environmental problems transcend a wide range of levels (i.e. across local, national, regional and global). The idea in that broad societal changes – which is described as the landscape level – can create opportunities for non-mainstream, radical practices and technologies at the niche level to replace the old social and technological mainstream practices at the regime level – the status quo in a specific domain of social and technological activity (Geels and Schot 2007). Many other theories of transformation applied to social-ecological systems share this general idea that some interplay between bottom-up change created by niche practices and top-down changes created by broad societal shifts, by changes in policies and economic activities, lead to transformation (Feola 2015; Patterson *et al.* 2017).

This can be illustrated for climate change and its impacts. First, the biophysical process plays out at different levels: global (CO<sub>2</sub> concentration), continental (weather patterns) and local (land-climate interactions). Second, levels also play a key role in terms of solutions. While, for example, international climate policy is negotiated at the global level, it needs to be implemented at the national and local levels. Connections across levels should therefore be a major consideration in environmental assessments and outlooks, and in recommended policies and actions (Zurek and Henrichs 2007). Mismatches between the levels of human-built and natural systems can lead to negative environmental impacts, for example, when a river basin falls under competing national jurisdictions (Cumming, Cumming and Redman 2006).

Integration across scales plays a significant role towards identifying synergistic and effective policies and actions (Palazzo *et al.* 2017). For example, the identification of concrete policy recommendations should consider what policy conditions have to be created (by governments, the private sector, civil society and others) to allow innovative bottom-up processes to flourish by scaling up to higher levels and deeply in future assessments (Moore, Riddell and Vocisano 2015; Mason-D’Croz *et al.* 2016). This implies that decision makers in different sectors receive useful information for formulating and implementing policies, strategies and investments that facilitate transformative change in their sector and area of interest.

The complementary features the top-down and bottom-up approaches being used in Part C allow the consideration of scales and their interactions in the evaluation of scenarios and strategies, by maximizing the synergies and, as much as possible, minimizing the trade-offs among them for potential pathways to achieving SDGs and other multilateral environmental agreements.

## 19.5 Roadmap for Part C of GEO-6

Building on previous assessments, particularly on GEO-5 (United Nations Environment Programme [UNEP] 2012), the focus of GEO-6 has shifted to a combination of the ‘what’ and ‘how’ questions, and the required approaches, to assess the state of scientific knowledge on the challenges and opportunities associated with global goals and targets. A universal, transformative and integrated agenda for sustainable development is now available in the form of the 2030 Agenda for Sustainable Development (without it being explicit about this), to allow the goals of a broad range of multilateral frameworks and agreements to be brought together in a more coherent manner. Part C seeks to address the synergies (co-benefits) and trade-offs (competing aspects) in achieving the multiple goals and targets of these frameworks and agreements (e.g. SDGs, Nationally Determined Contributions, Aichi biodiversity targets), rather than analysing how to achieve their many individual indicators separately. The guiding questions are:

- ❖ How can we achieve the environmental dimension of the SDGs and related multilateral environmental agreements?
- ❖ What mid- to long-term strategies are needed to achieve lasting sustainability?

The aim of the outlook chapters of GEO-6 (Part C of this report) is to address these questions by combining top-down, model-based scenario analysis with information resulting from bottom-up and participatory initiatives (see Section 19.2). The purpose is to illustrate how these can be used together towards meeting the information needs of decision makers at national and subnational as well as regional and global levels.

The following key elements are addressed in subsequent chapters:

- ❖ Formulating a quantitative long-term vision for 2050, consisting of key environmental targets from the SDGs and related multilateral environmental agreements (Chapter 20)
- ❖ Assessing long-term trends and discussing the potential implementation gaps (Chapter 21)
- ❖ Identifying potential pathways for achieving the long-term vision, with a specific focus on the many interrelations across the broad range of targets assessed (Chapter 22)
- ❖ Assessing innovative initiatives and game-changers in the context of future pathways (Chapter 23)
- ❖ Discussing the way forward for moving towards the theme of GEO-6 of healthy planet and healthy people (Chapter 24).

# Chapter 20

## A Long-Term Vision for 2050

**Coordinating Lead Author:** Paul Lucas (PBL Netherlands Environmental Assessment Agency)

**Lead Authors:** Mark Elder (Institute for Global Environmental Strategies), Detlef van Vuuren (PBL Netherlands Environmental Assessment Agency),

**Contributing Authors:** Fintan Hurley (Institute of Occupational Medicine)

## Executive summary

**To assess future progress towards achieving the Sustainable Development Goals (SDGs) and related Multilateral Environmental Agreements (MEAs), their underlying targets need to be translated into a more concise and quantitative set of targets** (*well established*). The SDGs cover a wide range of issues, with the environment represented in most of them, including in non-environmental goals. A range of challenges exists when interpreting the targets of the SDGs and related MEAs for an assessment of future progress. First, to make the assessment focused, a selection of the targets needs to be identified. Next, these targets need to be quantitative, using clear indicators accompanied by target values. {20.2; 20.3}

**SDGs can be structured into groups based on how they address human well-being, sustainable consumption and production, and the natural resource base** (*established, but incomplete*). The 2030 Agenda for Sustainable Development emphasizes that the goals and targets are integrated and indivisible and aimed at contributing to coherent sustainability policies. How the SDGs can be implemented synergistically is not apparent from the 2030 Agenda. To reveal potential trade-offs and synergies between achieving multiple SDGs and to point to ways these interlinkages can be governed, they can be grouped into goals focusing on social objectives or more broadly human well-being, goals addressing sustainable consumption and production with respect to resource use and access, and goals that address the protection and management of natural resources. These groups are bidirectionally connected in the sense that the environment provides the natural resource base on which human development and ultimately human well-being, including human health, are built. Unsustainable resource use can adversely impact both people and the planet, calling for policies that specifically focus on sustainable consumption and production as well as equitable distribution of natural resources and their benefits. The benefits to human health thus depend on the SDGs as a whole, not just those explicitly relating to health or well-being. {20.3}

**Environment-related SDG targets can be further quantified based on internationally agreed targets from Multilateral Environmental Agreements (MEAs) and the scientific literature** (*established, but incomplete*). Although many SDG targets have been formulated in clear and quantitative terms, for many environment-related ones, this is much less the case, both quantitatively and qualitatively. For several issues, such as climate change and biodiversity loss, the targets in MEAs are more concrete. Quantification of SDG targets can thus build on related MEAs. When internationally agreed environmental targets are lacking, so-called science-based targets can be used that are based on biophysical limits established in the scientific literature. {20.4}

**The scenario assessment of GEO-6 centres around the food-water-energy nexus, linked to the five GEO-6 environmental themes and related multidimensional poverty and health.** The selection of targets for the GEO-6 scenarios assessment, puts the use of natural resources central, focusing on the challenges addressed by, and linked to, the SDGs on food and agriculture (SDG 2), water (SDG 6) and energy (SDG 7). The use of natural resources is on the one hand linked to social objectives for people's access to food, water and energy, and subsequently to related health impacts (SDG 3). On the other hand, the use of natural resources is linked to the quality and quantity of the natural resource base that is required for, or impacted by, this use (SDG 13, SDG 14 and SDG 15). This focus and further quantification provide an integrated perspective on the environmental dimension of the SDGs and related agreements. The resulting set of targets is not an alternative to what is globally agreed, but a subset, and sometimes a proxy, to be used for the analysis in subsequent chapters. {20.4}

## 20.1 Introduction

An analysis of pathways towards sustainable development needs a long-term vision. Ideally, such a vision is summarized in a quantitative set of globally agreed key objectives or targets. The 2030 Agenda for Sustainable Development, adopted in September 2015, conceptualizes sustainable development through 17 SDGs and is further operationalized through 169 targets and 232 indicators (United Nations 2015a; see Annex 4-1). The Agenda formulates an ambitious and transformational vision for 2030. The SDGs address a broad range of issues, including eradicating poverty, transforming towards sustainable and resilient societies, and protecting and managing the natural resource base. Furthermore, the SDGs and its targets are related to several Multilateral Environmental Agreements (MEA). Together, the SDGs and related MEAs provide a globally agreed set of targets to guide the transformation towards long-term sustainability.

In this chapter, we define the vision used for the scenario analysis of GEO-6, taking a long-term perspective, beyond 2030. This vision uses the SDGs as an overarching, integrated set of goals and targets to start from, selecting key environment-related targets, and, where relevant, further quantifying these with targets from related MEAs or the scientific literature. This long-term vision addresses the theme of GEO-6 – Healthy Planet, Healthy People – by focusing on global environmental targets linked to the five themes discussed in Part A (State of the Global Environment), and related multidimensional poverty and health targets. In Chapters 21 and 22 the existing scenario literature is assessed, to allow discussion of future developments with respect to these targets and the pathways towards achieving them.

## 20.2 The environmental dimension of the SDGs

In 1972, as part of the United Nations Conference on the Human Environment, countries worldwide agreed that natural resources should be safeguarded, and pollution should not exceed the environment's capacity to clean itself (United Nations 1972). Since 1972, a proliferation of United Nations conferences, summits and international agreements have set targets for environmental protection and sustainable human development (Jabbour *et al.* 2012). The years 2015 and 2016 were a landmark for environmental multilateralism, thanks in large part to the formulation and adoption of five global frameworks, including the Paris Agreement (United Nations Framework Convention on Climate Change [UNFCCC] 2015) and the 2030 Agenda for Sustainable Development (United Nations 2015a).

The 2030 Agenda for Sustainable Development is explicit about the integrated nature of its goals and targets. The SDGs cover a wide range of environmental issues (see Section 1.5), with the environment represented in most of them (Organisation for Economic Co-operation and Development [OECD] 2015; United Nations Environment Programme [UNEP] 2015; Lucas *et al.* 2016; Reid *et al.* 2017) including their non-environmental goals (Elder and Olsen 2019).

More than half of the SDGs have an environmental focus and/or address the sustainability of natural resource use, while most include at least one target concerning environmental sustainability (United Nations Environment Assembly of the United Nations Environment Programme [UNEA] 2016). These targets link to the quality of the physical environment either directly (i.e. air, climate, biodiversity, oceans, land and freshwater) or indirectly (e.g. via health, education, agriculture, drinking water and sanitation, energy, and governance and institutions). Twelve SDGs promote human well-being through the sustainable use of natural resources, and ten can be achieved only if the efficiency of natural resource use is substantially improved (UNEP 2015). However, although many SDG targets have been formulated in clear and quantitative terms, many environment-related ones are not (Gupta and Vegelin 2016; Elder and Olsen 2018). This makes it more difficult to define a set of environment-related targets to be assessed in a quantitative scenario analysis.

## 20.3 An integrated view on the SDGs

The 2030 Agenda for Sustainable Development emphasizes that the goals and targets are integrated and indivisible, and aim to contribute to coherent sustainability policies (United Nations 2015a) – meaning that they depend on each other in different ways (Nilsson, Griggs and Visbeck 2016). Greater focus on the interlinkages and synergies among the SDGs could enhance the effectiveness of their implementation and reduce the total burden and cost of pursuing the goals and targets individually (Elder, Bengtsson and Akenji 2016; UNEA 2016). However, while the SDGs and their associated targets are fairly straightforward, how they can be integrated is not apparent from the 2030 Agenda (International Council for Science and International Social Science Council 2015). The systemic properties of an integrated and holistic approach are also poorly understood (Weitz *et al.* 2017). Nevertheless, the scientific community at large has called for an integrated approach for SDG implementation (Weitz, Nilsson and Davis 2014; United Nations 2015b; Boas, Biermann and Kanie 2016; Lucas *et al.* 2016; Yillia 2016; Stafford-Smith *et al.* 2017). Frameworks have been proposed that allow the interactions between the goals and targets to be mapped and scored (Nilsson *et al.* 2016; Nilsson, Griggs and Visbeck 2016; International Council for Science 2017; Weitz *et al.* 2017; Zhou, Moinuddin and Xu 2017; Singh *et al.* 2018).

Various studies have analysed the interlinkages between the goals and targets, from different perspectives and using different methodologies, for example, by looking at the goals and targets as a network in which links among goals exist through targets that refer to multiple goals (International Science Council and International Social Science Council 2015; Le Blanc 2015; UNEP 2015; Zhou and Moinuddin 2017) and are based on quantitative modelling (United Nations 2015b; van Vuuren *et al.* 2015; Collste, Pedercini and Cornell 2017). Furthermore, researchers have created frameworks to structure the goals, to reveal potential trade-offs and synergies, and to point to ways their interactions might be governed (Griggs *et al.* 2013; Nilsson, Lucas and Yoshida 2013; Lucas *et al.* 2014; Waage *et al.* 2015a; Waage *et al.* 2015b; Elder, Bengtsson and Akenji 2016; Folke *et al.* 2016; Gupta and Vegelin 2016; Reid *et al.* 2017).

Overall, these frameworks reveal a nested structure of goals (**Figure 20.1**). Some focus on social objectives, related to lives and livelihoods or *human well-being* (SDGs 1, 3, 4, 5, 10); others address *sustainable consumption and production* from a resource use or security perspective (SDGs 2, 6, 7) or more broadly, such as in the context of industry or cities (SDGs 8, 9, 11, 12); and some goals address global public goods from an environmental perspective or the *natural resource base* (SDGs 13, 14, 15). Finally, these goals are supported by a goal on governance (SDG 16) and one addressing means of implementation (SDG 17).

The way of structuring links to the central theme of GEO-6, with Healthy People at the top (being part of human well-being) and Healthy Planet at the bottom (natural resource base). The groups of SDGs are bidirectionally connected in the sense that a healthy planet is the foundation for the economy, human development and, ultimately, human well-being, including healthy people. Unsustainable resource use, waste and pollution can impact adversely on both the natural resource base and on human well-being. A key role is thus played by the goals in the middle, addressing sustainable production and consumption and the equitable distribution of goods and services.

**Figure 20.1: A framework for the classification and grouping of the SDGs**

Source: PBL Netherlands Environmental Assessment Agency (2017).

The structure in **Figure 20.1** loosely follows the five areas of critical importance mentioned in the preamble of the 2030 Agenda for Sustainable Development – people, prosperity and planet, underpinned by peace and partnership (United Nations 2015a). It also shows similarities with the doughnut model proposed by Raworth (2012; 2017); a doughnut-shaped area between two boundaries: a social floor (human well-being) and an environmental boundary (the natural resource base). The doughnut model highlights the dependence of human well-being on a healthy environment and stresses the need for improved equity in incomes and resource use, and greater efficiency in the latter (Raworth 2017). Finally, the structuring also relates to the triangle or pyramid originally proposed by Herman Daly, which moves from a base of ultimate means to a tip of ultimate ends, and integrates human well-being, economic development and the state of natural resources into a holistic framework (Daly 1973; Meadows 1998; Pinter *et al.* 2014). According to this framework, ultimate means refer to the underlying natural resource base and the life-support system of the planet (equivalent to the bottom circle in **Figure 20.1**, the natural resource base); intermediate means involve the material economy (middle circle, sustainable consumption and production); intermediate ends represent the capacities of individuals and the condition and functioning of institutions (top circle; human well-being); and ultimate ends indicate human well-being or happiness (Pinter *et al.* 2014).

It should be noted that most SDGs can be classified within different groups, since each SDG is operationalized by multiple targets. SDG 2, for example, includes targets related to human well-being (such as reducing hunger and malnutrition), to sustainable resource use (such as promoting sustainable agriculture), and to the natural resource base (such as maintaining agricultural biodiversity). The structuring of the SDGs in **Figure 20.1** follows from an interpretation from the environmental perspective. In the case of SDG 2, this is sustainable agriculture.

Although it is not stated explicitly, the 2030 Agenda for Sustainable Development and the SDGs suggest sustainable development to be the overarching goal, while emphasizing poverty eradication (Elder, Bengtsson and Akenji 2016). As such, many SDGs are means or intermediate steps towards achieving the goal of poverty eradication (i.e. human health, well-being and security). The top circle therefore contains the people-centred or social goals that aim to deliver individual and collective well-being through improved health and education, ensuring equitable distribution within and between individuals and countries (Waage *et al.* 2015a). These goals can be considered minimum standards for human well-being, while there are also synergistic opportunities for implementation, between education, health and gender equality for example.

Achieving these people-centred goals depends strongly on the realization of goals that address sustainable consumption and production, and equitable distribution of goods and

services, including food, water and energy, and more broadly the economy, infrastructure, cities and industries. Food, water and energy security are important resources needed to achieve social objectives such as poverty reduction and good health. The goals addressing these resource needs encompass two distinct resource aspects: (i) access to resources, relevant for poverty reduction, and (ii) sustainable use of resources, relevant for the long-term security of supply. At the same time, production of food, water and energy is highly interlinked. Water is needed for food and energy production, for example, and energy is needed to produce water and food. This is the so-called food-water-energy nexus (Hoff 2011; (Food and Agriculture Organization of the United Nations [FAO] 2014)). These resource goals are accompanied by economy-focused goals that address the production of goods and services more broadly for achieving social objectives. These latter goals focus on the economic system (economic growth and jobs), infrastructure and sustainable industrialization, human settlements, and sustainable consumption and production in general. From an environmental perspective, these goals address the decoupling of efforts to improve human well-being from negative effects on the natural resource based in different contexts.

Realization of these second-level resource and economy goals depends on conditions in the biophysical systems or the natural resource base, including climate, oceans, land and biodiversity (parts of SDG 6 on freshwater also fit here). These goals address protection, conservation, restoration and sustainable use of critical parts of the Earth system. They directly relate to the biophysical limits to ensuring long-term environmental sustainability, or planetary boundaries (Rockström *et al.* 2009; Steffen *et al.* 2015).

The goals in the middle circle connect environmental issues (such as biodiversity loss, climate change and ocean acidification) and social themes (such as health, equal opportunities and labour conditions) to economic activities, products and markets. The challenge of these goals is to seize the synergies and reduce the potential trade-offs between those goals aiming to eradicate poverty and improve human well-being versus those addressing the natural resource base. In other words, improving human well-being should not be achieved at the expense of the natural resource base, while safeguarding the planet should benefit all people and not interfere with poverty eradication. In addition, these goals in the middle are faced with the competition for resources needed to serve multiple goals, e.g. land, water and energy resources. A major transformation to more sustainable consumption and production is needed to address these challenges. From a production perspective, this requires a decoupling of economic growth from environmental degradation, including cleaner production processes, and improved resource efficiency and corporate responsibility. From a consumption perspective it requires changes in lifestyles, consumption preferences and consumer behaviour (Bizikova *et al.* 2015).

## 20.4 A long-term vision: selected targets and indicators

A range of challenges exist when interpreting SDG targets and related indicators with regard to their values. Assessing future developments and potential pathways for achieving all SDG targets is not possible because of limited data and time. Furthermore, such an analysis is limited by the scope of the existing scenario literature and the integrated assessment models that these studies are built on (see Chapter 21). A selection of targets should thus be made. Next to the challenge of selecting targets, many environment related SDG targets are broadly defined and/or phrased in non-quantitative terms (Lucas *et al.* 2016). In order to assess pathways towards achieving the environmental dimension of the SDGs, the selected targets need to be quantitative, requiring clear indicators accompanied by target values.

The grouping of SDGs in **Figure 20.1** was used to select and organize the SDG targets. Quantitative targets from related MEAs and the scientific literature (science-based targets) were used to quantify these targets, where relevant. The selection is centred around the so-called food-water-energy nexus, focusing on the challenges addressed by, and linked to, the SDGs on food and agriculture (SDG 2), water (SDG 6) and energy (SDG 7). The selection puts natural resource use at the centre (*sustainable consumption and production*), linked with social objectives concerned with people's access to these resources and related health impacts (*human well-being*), and environmental objectives related to the quality and quantity of environmental resources required for or impacted by human use (*natural resource base*). The selected SDG targets for *human well-being* (**Table 20.1**) and the *natural resource base* (**Table 20.2**) are endpoint targets, aiming for a healthy planet with healthy people. The selected SDG targets for *sustainable consumption and production* (**Table 20.3**) are effort- or activity-related targets that are relevant to achieving the endpoint targets.

The selected targets addressing the natural resource base link to the five environmental themes discussed in Part A of GEO-6 (air, biodiversity, oceans, land and freshwater), supplemented by climate change. Furthermore, the targets link to a range of GEO-6 cross-cutting issues (see Chapter 4), most prominently health, climate change, energy, and food systems. Chemicals, and waste and wastewater are two other GEO-6 cross-cutting issues, identified as issues of global concern and addressed under multiple SDGs. There is a general lack, however, of future chemicals and waste flow studies and scenarios in the scientific literature (**see Box 21.1**). Therefore, chemicals, and waste and wastewater are not discussed as separate issues. More in-depth analysis of these two issues in the context of the SDGs can be expected in UNEP's upcoming Global Chemicals Outlook II and Global Waste Management Outlook, to be released in 2019.

For each target selected, one indicator (and where relevant, two) is selected to track progress. In the context of the SDGs, the United Nations General Assembly adopted an SDG indicator framework that consists of 232 indicators (United Nations 2017). Each indicator is being developed in order to provide

accurate and reliable data from now until at least 2030. UNEP is the custodian agency for several SDG indicators related to water (SDG 6), sustainable consumption and production (SDG 12), conservation and sustainable use of ocean resources (SDG 14) and of terrestrial ecosystems (SDG 15) (United Nations 2018). In addition to being custodian agency for these SDG indicators, UNEP is involved in most other SDG indicators that have an environmental dimension. The selected indicators link as much as possible to these globally agreed indicators.

It should be noted that the selected indicators are meant to track progress at the global level and that they are not always relevant at the national or subnational scale. Moreover, many indicators, especially those related to *sustainable consumption and production* and the *natural resource base*, cover only part of what the goals and targets try to accomplish. For air quality in cities, for example, the proposed indicator tracks progress for only one kind of air pollutant (i.e. fine particulate matter [PM] of diameter less than 2.5 µm and 10 µm; PM<sub>2.5</sub> and PM<sub>10</sub>) – yet there are several others, with some interacting with each other (e.g. ozone, volatile organic compounds, sulphur dioxide etc.). With respect to health, only one indicator was selected (the under-five mortality rate), which only partly reflects the interconnectedness of planet, society and human health that the SDGs, and GEO-6, are trying to represent. Focusing on a single indicator to track progress for such targets should thus be done with care. To keep the analysis focused however, a limited set of targets is selected to cover, as much as possible, the food-water-energy nexus, while the selected indicators are based mostly on the official SDG indicator set.

Next to the indicator and target levels presented in **Tables 20.1**, **20.2** and **20.3**, additional indicators are used in Chapters 21 and 22 to discuss future development of the respective targets, including relevant underlying developments, as well to discuss the potential of specific measures and important synergies and trade-offs across these measures and the selected targets.

### 20.4.1 Human well-being

For *human well-being*, five SDG targets are selected (**Table 20.1**). Overall, the SDGs express a strong commitment, both quantitatively and qualitatively, to eradicating poverty and improving human well-being. Among other relevant issues, they aim to end all forms of poverty, including ending hunger, and to achieve access for all to safe drinking water, adequate sanitation, modern energy services, health care, education, work, housing and more.

Despite the centrality of human health to the GEO-6 theme of Healthy Planet, Healthy People, only one target (3.2) and one indicator (3.2.1, under-five mortality rate) has been selected for the scenario analysis. Under-five mortality is generally seen as a good indicator of quality of life, is influenced by numerous environmental determinants, is strongly related to other targets selected for human well-being. And the SDGs set a quantitative target for 2030. Scenario projections, although limited, also exist in the scientific literature that link future developments in under-five mortality to underlying environmental risk factors (see Section 21.3.6). The under-five mortality rate also has

**Table 20.1: Selected targets and indicators for human well-being**

| SDG target                                                                                                                                                                                                                                                              | Target for GEO-6                                                        | Related MEA | Indicator *                                                                        | Target level         | Based on | Cluster in Chapters 21 and 22            |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------|-------------|------------------------------------------------------------------------------------|----------------------|----------|------------------------------------------|
| <b>2.1 By 2030, end hunger and ensure access by all people, in particular the poor and people in vulnerable situations, including infants, to safe, nutritious and sufficient food all year round</b>                                                                   | End hunger                                                              | –           | 2.1.1 Prevalence of undernourishment                                               | 0 in 2030            | SDGs     | Agriculture, food, land and biodiversity |
| <b>3.2 By 2030, end preventable deaths of newborns and children under 5 years of age, with all countries aiming to reduce neonatal mortality to at least as low as 12 per 1,000 live births and under-five mortality to at least as low as 25 per 1,000 live births</b> | End preventable deaths of children under 5                              | –           | 3.2.1 Under-five mortality rate                                                    | < 25 in 2030         | SDGs     | Human health                             |
| <b>6.1 By 2030, achieve universal and equitable access to safe and affordable drinking water for all</b>                                                                                                                                                                | Achieve universal access to safe drinking water and adequate sanitation | –           | 6.1.1 Proportion of population using safely managed drinking water services        | 100 per cent in 2030 | SDGs     | Freshwater                               |
| <b>6.2 By 2030, achieve access to adequate and equitable sanitation and hygiene for all and end open defecation, paying special attention to the needs of women and girls and those in vulnerable situations</b>                                                        |                                                                         | –           | Proportion of population using safely managed sanitation services (6.2.1)          | 100 per cent in 2030 | SDGs     | Freshwater                               |
| <b>7.1 By 2030, ensure universal access to affordable, reliable and modern energy services</b>                                                                                                                                                                          | Achieve universal access to modern energy services                      | –           | 7.1.1 Proportion of population with access to electricity                          | 100 per cent in 2030 | SDGs     | Energy, air and climate                  |
|                                                                                                                                                                                                                                                                         |                                                                         | –           | 7.1.2 Proportion of population with primary reliance on clean fuels and technology | 100 per cent in 2030 | SDGs     | Energy, air and climate                  |

MEA = multilateral environmental agreement

significant limitations, however. It excludes measures of morbidity, for example, including psychosocial aspects of childhood well-being (e.g. a sense of safety and of being loved) and other aspects of childhood health that may affect health and survival in later life (see Section 4.2.1). However, these latter data could not be gathered routinely and reliably worldwide, let alone for inclusion in a scenario context. Finally, by being age-limited, the under-five mortality rate does not account for other vulnerable populations, such as older people or pregnant women. As a result, child mortality only partly represents the effect on human health of the many and varied policies and measures, whether business-as-usual ones or transformative scenarios, that are discussed in the following chapters.

SDG target 3.9 is more specific on particular environment-related health risk factors, targeting a substantial reduction in the number of deaths and illnesses from hazardous chemicals and from air, water and soil pollution and contamination. The specific indicators associated with this target involve the mortality rate attributable to household and ambient air pollution, deaths due to unsafe water, sanitation and hygiene and mortality from unintentional poisoning. These rates are largely a reflection of the pollution levels themselves. In effect, control of mortality implies control of pollution itself, which is the focus of several of the targets here, as well as that of several of the SDG targets selected for the *natural resource base*. And so, achievement of all of these targets is an essential part of the GEO-6 vision of Healthy Planet, Healthy People.

## 20.4.2 Natural resource base

For the *natural resource base*, nine SDG targets are selected that relate to the quality and quantity of environmental resources (i.e. air, climate, biodiversity, oceans, land and freshwater) (**Table 20.2**). Compared with human well-being, none of these targets has clear quantitative target levels that could be used in a scenario analysis. Each aims to “halt” or “combat” a specific type of environmental degradation and to “restore” the natural system as much as possible.

Several natural resource targets link explicitly or implicitly to specific MEAs that have more explicit quantitative targets and/or take a longer-term perspective, beyond 2030. For these targets, the target levels can be based on quantitative measures given by the agreements. SDG 13 on climate change includes only process- or activity-based targets, but explicitly refers to the United Nations Framework Convention on Climate Change (UNFCCC) as the primary international intergovernmental forum for negotiating the global response to climate change. The target for climate change is thus based on the globally agreed target of the Paris Agreement: that is, “Holding the increase in the global average temperature to well below 2°C above pre-industrial levels and pursuing efforts to limit the temperature increase to 1.5°C above pre-industrial levels” (UNFCCC 2015). The World Health Organization (WHO) established an air-quality guideline of 10 µg/m<sup>3</sup> for annual mean PM<sub>2.5</sub> concentrations (WHO 2006), but also defined interim targets of 15 µg/m<sup>3</sup>, 25 µg/m<sup>3</sup> and 35 µg/m<sup>3</sup>. Here, we focus on the long-term effects of PM<sub>2.5</sub> and use the percentage of the population exposed to annual mean PM<sub>2.5</sub> concentrations above the highest interim target of 35 µg/m<sup>3</sup> as the indicator for achieving the target for air quality. For biodiversity loss, the SDG target does not include a target year for ending biodiversity loss. We derived the target from the Convention on Biological Diversity’s strategic plan for biodiversity 2011–2020, and more specifically Aichi biodiversity target five: “By 2020, the rate of loss of all natural habitats, including forests, is at least halved and where feasible brought close to zero...” (Convention on Biological Diversity 2010). This target was translated by Kok *et al.* (2018, p. 138) into halting “biodiversity loss by 2020 for developed countries and from 2030 onwards for developing countries”. Kok *et al.* (2018) use mean species abundance as a biodiversity-impact indicator to track progress on this target (Alkemade *et al.* 2009). Mean species abundance is a measure of the intactness of an ecosystem relative to its undisturbed state. Specifically, it is the mean change in the abundance of the species that were present in the original, undisturbed state. Although it is different from the Living Planet Index (the SDG indicator for target 15.5), it shares some important conceptual similarities.

When related MEAs do not exist or lack quantitative target levels, target levels could also be based on scientific literature. The planetary boundaries framework is one example (Hoff and Alva 2017; Lucas and Wilting 2018) – it proposes global quantitative limits for human disturbance of nine critical Earth-system processes (Rockström *et al.* 2009; Steffen *et al.* 2015). Crossing any of the boundaries at the global scale increases the risk of large-scale, and possibly abrupt or irreversible, environmental change. The planetary boundary framework thus provides a quantification of safe levels of global environmental change, based on Earth-system science.

The global limits from the planetary boundaries literature are used for targets related to freshwater quality (de Vries *et al.* 2013; Steffen *et al.* 2015), and ocean acidification (Steffen *et al.* 2015). As already noted, studies and scenarios for chemicals and waste flow are largely missing from the scientific literature. The selected targets for freshwater quality and marine pollution therefore focus on nutrient losses (of nitrogen and phosphorus), for which scenario literature, although limited, is available. Excessive nutrient losses through run-off and erosion can cause the eutrophication of freshwater and coastal ecosystems (de Vries *et al.* 2013; Steffen *et al.* 2015). While recognizing that regional distribution is critical to impacts, the two targets for freshwater quality are global averages. There are several other limitations in using these target levels. They do not account for future trends in the efficiency of nutrient use and do not include other relevant sources of pollution, primarily untreated sewage. Ocean acidification lowers the saturation state of aragonite, a form of calcium carbonate, making it more difficult for marine organisms to form shells and skeletons, which can also run the risk of dissolving as a result of the acidification. Taking into account geographic heterogeneity, the global target for ocean acidification is set for the average global surface aragonite saturation level (Steffen *et al.* 2015).

It should be stressed that the planetary boundaries are not politically endorsed and are subject to ongoing scientific debate. In the end, defining safe levels of global environmental changes and getting consensus on them is a political process, involving subjective elements such as risk acceptance, solidarity and precaution (Lucas and Wilting 2018). Here, the global limits defined by the planetary boundaries framework are used as a set of science-based targets. It should further be noted that there is large geographic heterogeneity underpinning these Earth-system processes that should also be monitored.

For the selected targets for water scarcity, marine nutrient pollution, ocean resources and land degradation, no globally agreed or scientific quantitative target level is available. Therefore, for these targets no quantitative target level is set. The SDG indicator for water scarcity is freshwater withdrawal as a proportion of available freshwater resources (SDG indicator 6.4.2). As this indicator is only relevant at the local level, the total global population living in water scarce areas is used as an indicator. For marine nutrient pollution, the SDG indicator is an index of Coastal Eutrophication (ICEP) and Floating Plastic Debris Density. The indicator is still under development. Here, the focus is on coastal eutrophication, using nutrient runoff into oceans (N and P) as indicator to track progress. For sustainable management of ocean resources, trends in the proportion of fish stocks within biologically sustainable levels, the SDG indicator, are used to track progress. The SDG indicator for land degradation is the proportion of land that is degraded over total land area, based on three sub-indicators, namely trends in land cover, land productivity and carbon stocks (United Nations Convention to Combat Desertification [UNCCD] 2017; van der Esch *et al.* 2017). Also this indicator is still under development. Recognizing that all three sub-indicators are important for assessing land degradation, trends in soil organic carbon stock are selected to track progress.

**Table 20.2: Selected targets and indicators for the natural resource base**

|                                                                                                                                                                                                                                                                                                                                                                                      |                                     |                                      |                                                                                             |                                         |                                        |                                          |

### 20.4.3 Sustainable consumption and production

For *sustainable consumption and production*, five SDG targets are selected that address the decoupling of economic growth from environmental degradation (see **Table 20.3**: Selected targets and indicators for sustainable production and consumption). These SDG targets are mostly not quantitative – aiming to increase efficiency substantially without defining a specific target level. They address efforts or activities that help to achieve the endpoint targets. Their absolute level depends on specific overarching objectives. Yield improvements, for example, are important for achieving targets on hunger and biodiversity (SDG targets 2.1 and 15.5). Improvements in water-

use efficiency are important for achieving the target on water stress targets (SDG target 6.4). And improvements in energy efficiency and the renewable energy share are important for achieving the target on climate change (SDG 13). The level of decoupling required thus depends on these endpoint targets. Therefore, for the selected SDG targets for *sustainable consumption and production*, no quantitative target levels are defined. Also not for SDG target 7.3, to “double the global rate of improvement in energy efficiency”. Instead, the pathways analysis of Chapter 22 provides ranges for the efforts required to achieve the selected SDG targets that address human well-being and the natural resource base, taking into account the interdependencies across these efforts.

**Table 20.3: Selected targets and indicators for sustainable consumption and production**

| SDG target                                                                                                                                                                                                                                                                                                                                                                           | Target for GEO6                        | Related MEA | Indicator *                                                        | Target level                                                     | Based on | Cluster in Chapters 21 and 22            |

MEA = multilateral environmental agreement

## 20.5 Conclusions

The SDGs and related MEAs provide a long-term vision for sustainable development to influence policies at the global, regional, national and local levels. This chapter makes a selection of SDG targets, linked to targets from related MEAs and the scientific literature (science-based targets) where relevant, accompanied by clear indicators and quantitative target values, at the global level. The resulting target set provides an integrated perspective on the environmental dimension of the SDGs, focusing on the GEO-6 environmental themes in Part A (air, biodiversity, oceans, land and fresh water) and related multidimensional poverty (access to food, water and energy, and under-five mortality). Unlike the SDGs and related MEAs, the science-based targets selected when there are no globally agreed quantitative targets - are not politically

endorsed. They provide a proxy for the related SDG ambitions. Finally, for some selected targets no quantitative globally agreed or science-based target is currently available.

The selection of targets is analysed further in subsequent chapters: Chapter 21 discusses the implementation gap if no new policies are formulated, and Chapter 22 discusses pathways towards achieving the targets, including relevant interrelations (synergies and trade-offs) between different measures and targets. The two chapters do not address regional, national or local differences in developments for these targets and the implementation of measures for achieving them. Chapter 23 discusses implementation from a bottom-up perspective, thereby explicitly taking into account the local situation, different actors and cultural perspectives.

# Chapter 21

## Future Developments Without Targeted Policies

**Coordinating Lead Author:** Paul Lucas (PBL Netherlands Environmental Assessment Agency), Steve Hedden (Frederick S. Pardee Center for International Futures), Detlef van Vuuren (PBL Netherlands Environmental Assessment Agency)

**Lead Author:** Katherine V. Calvin (Joint Global Change Research Institute/ PNNL), Serena H. Chung (United States Environmental Protection Agency), Mike Harfoot (United Nations Environment Programme World Conservation Monitoring Centre (UNEP-WCMC)), Alexandre C. Köberle (Universidade Federal do Rio de Janeiro), Jonathan D. Moyer (Frederick S. Pardee Center for International Futures), Yoshihide Wada (International Institute for Applied Systems Analysis)

**Contributing Authors:** Barry B. Hughes (Frederick S. Pardee Center for International Futures), Fintan Hurley (Institute of Occupational Medicine), Terry Keating (United States Environmental Protection Agency)

**GEO Fellow:** Katrina Lyne (James Cook University)

## Executive summary

**Together with other tools, model-based scenario analysis provides a useful method to explore whether environment related targets of the Sustainable Development Goals (SDGs) and related Multilateral Environmental Agreements (MEAs) are going to be achieved** (*well established*). Assessing whether current trends are leading to fulfilment of the selected targets outlined in Chapter 20 is complex: it requires insights into the interactions of different trends and systems, inertia and cross-scale relationships. A combination of qualitative storylines and quantitative scenario tools can help to explore possible futures trends, while taking the many complexities into account. While scenarios can never be forecasts, because surprises may occur, they can inform decision makers of the likely implications of current trends. {21.2}

**An assessment of the scenario literature concludes that a continuation of current trends will probably not lead to fulfilment of selected environment related targets of the SDGs and related MEAs** (*well established*). **While some improvement is projected for indicators related to human development – albeit not fast enough to meet the targets – those related to the natural resource base are projected to move further in the wrong direction** (*established, but incomplete*). Projected ongoing population growth, and economic development imply that the demand for food, water and energy will strongly increase towards 2050. At the same time, business-as-usual scenarios show a clear improvement over time in reducing hunger, increasing access to safe drinking water and adequate sanitation, and increasing access to modern energy services, but not fast enough to meet the related SDG targets by 2030. Furthermore, although projected improvements in resource efficiencies across the board (agricultural yields, nutrient use efficiency, water use efficiency and energy efficiency) will somewhat limit the impacts of resource use on the environment, these improvements are not enough to reduce the pressure on already stressed environmental systems. As a result, trends in environmental degradation are projected to continue at a rapid rate. Related targets are not achieved. {21.4}

**Under current trends, environmental pressures related to the agricultural and food system will further increase** (*well established*). As the global population and per capita incomes are projected to grow, both per capita and total food consumption expected to rise. At the same time, the number of undernourished people is projected to decline to 300-650 million in 2030, a figure that still significantly exceeds the target for ending global hunger. Furthermore, food production and land use are directly related to many environmental problems. Global agricultural demand is projected to increase by 50-60 per cent. Over the last decades, around four-fifth of the increase in food demand was met by agricultural intensification, and one-fifth by an increase in agricultural area. This trend is expected to more or less continue. Together, food production systems will continue to contribute to land expansion, increasing water demand and nutrient runoff, biodiversity loss and land degradation. Related targets are not achieved. {21.3.2}

**Without new policies, the objectives of the Paris Agreement are not achieved** (*well established*). Primary energy supply is projected to grow by 50-70 per cent between 2010 and 2050. Moreover, fossil fuels are expected to remain prominent in the world energy system. As a result, energy use is expected to continue to be the main cause of greenhouse gas (GHG) emissions. In addition, the agricultural systems and land use will continue to contribute to GHG emissions. Current and planned climate policies, as formulated by different countries under the Paris Agreement of the United Nations Framework Convention on Climate Change, are expected to lead, at best, to a stabilization of emissions. This is considerably less than would be needed to achieve the objectives of the Paris Agreement, i.e. to keep the temperature well below 2°C, and if possible below 1.5°C. Achieving these objectives would require an almost complete decarbonization of the energy system. {21.3.3}

**Ambient air pollution is expected to continue to contribute to millions of premature deaths in the coming decades** (*established but incomplete*). There are different forms of urban and regional air pollution. Exposure to ambient fine particulate matter (PM<sub>2.5</sub>) is estimated to have caused approximately 4 million premature deaths in 2016 and can be used as an indicator of adverse health effects of ambient air pollution. Without stringent policies to control air pollution, ambient PM<sub>2.5</sub> concentrations are expected to increase. Most trend scenarios assume that past trends of stricter air pollution policies coupled with increasing incomes continue in the future, i.e. that more stringent air pollution policies are applied in developing countries as their incomes increase, thereby projecting a slow decrease in emissions of PM<sub>2.5</sub> and its precursors in most global regions. However, this trend would still not be sufficient to reduce PM<sub>2.5</sub> concentrations below the least stringent air quality target of the World Health Organization (WHO) in large parts of Asia, the Middle East and Africa, resulting in 4.5 to 7 million premature deaths globally by mid-century {21.3.3}

**Global water scarcity and the population affected by it are expected to increase** (*established, but incomplete*). Global human water demand is projected to increase by around 25 to 40 per cent this century. The rise is primarily driven by rapid population growth and increased industrial activities (higher electricity and energy use) in developing countries. An increase in irrigated area and irrigation intensity is also projected, but its effect will probably be compensated by improvements in irrigation efficiency in regions with strong economic development. Changing rainfall patterns will exert additional pressure on regional water availability. By 2050, the Asian population living in areas exposed to severe water stress is projected to increase by around 50 per cent compared with 2010 levels, putting severe pressure on non-renewable groundwater reserves. {21.3.4}

**Oceans are expected to continue to be polluted and overexploited** (*established, but incomplete*). Nutrient (nitrogen and phosphorus) flows from freshwater into world oceans exceed sustainable levels and as a result the risks of dead zones and toxic algae blooms in coastal areas are projected to increase. This is largely related to increased fertilizer use in agricultural production and developments in wastewater treatment that are lagging behind improvements in access to sanitation. As a result of an increasing concentration of carbon dioxide (CO<sub>2</sub>), oceans are expected to further acidify, negatively affecting marine organisms' ability to create shells and skeletons or even resulting in their dissolution. Acidification is expected to increase most rapidly in polar regions. Finally, under current fishing strategies, the projected increase in demand for fish is expected to reduce the proportion of fish stocks that remain at biologically sustainable levels. {21.3.5}

**Preventable environmental health risks are projected to remain prominent in 2030, with related negative impacts on child mortality** (*established, but incomplete*). Nearly one-quarter of all deaths globally in 2012 can be attributed to environmental factors, with a greater portion occurring in vulnerable populations (children and the elderly) and in developing countries. Prominent environmental risk factors – i.e. exposure to ambient air pollution, and not having access to clean water, adequate sanitation or modern energy services – together with global hunger are expected to improve towards 2030, but not fast enough to achieve related targets in all countries. Related global child mortality is projected to decline, but not enough to achieve the SDG targets in many developing countries. Especially in sub-Saharan Africa, child mortality rates remain high, with a continued, although smaller, share related to preventable environmental risk factors. {21.3.6}

## 21.1 Introduction

Chapter 20 provided an overview of environment related targets that the international community committed to support, based on the Sustainable Development Goals (SDGs) and a range of Multilateral Environmental Agreements (MEAs). This chapter examines the international scenario literature to assess to what extent current and long-term trends are in line with achieving these targets, and to understand and highlight potential implementation gaps.

## 21.2 Global environmental scenarios

Environmental and sustainable development targets are usually formulated for a time period somewhere in the future. In an effort to inform decision makers concerned with global environmental and sustainability challenges, Global Environmental Assessments (GEA) explore possible futures, with a special focus on investigating the consequences of current trends and assessing whether the committed goals and targets are going to be met (Clark, Mitchell and Cash 2006; van Vuuren *et al.* 2012). This is not straightforward: clearly, no one knows which path the world will take in the next 40 years, and world views influence our expectations of this path. Assessments deal with the outlook component and the uncertainty involved in different ways. Some use a reference scenario that captures a likely future state. Others use multiple scenarios reflecting different storylines. In all cases, the scenarios are “plausible descriptions of how the future developments might evolve, based on a coherent and internally consistent set of assumptions (“scenario logic”) about the key relationships and driving forces (i.e. the technology, economy, environment interplay)” (Nakicenovic *et al.* 2000). Often a storyline is quantified within a model. While model-based quantification can help to take account of the many relationships that exist across scales, between regions, in time and across various sectors and environmental problems, the storyline elements help to ensure consistency for other elements that are more difficult to quantify. The main purpose of this scenario methodology is to be as scientifically rigorous as possible, while providing policy relevant information (van Vuuren *et al.* 2012).

Over the past few years, a large number of environmental assessment reports has been published. Many of these focus on specific environmental issues, such as climate change (Intergovernmental Panel on Climate Change [IPCC] 2014a), biodiversity loss (Secretariat of the Convention on Biological Diversity [SCBD] 2014) and the management and restoration of land resources (United Nations Convention to Combat Desertification [UNCCD] 2017). These can ensure the input

of scientific information into decision-making processes for the three Rio conventions, i.e. UNFCCC, CBD and UNCCD, respectively. Other environmental assessments have a less clear focus on specific decision-making processes. More sectoral environmental assessments address key drivers of environmental change, for example, the global energy system (Global Energy Assessment [GEA] 2012; International Energy Agency [IEA] 2017a) and the global agricultural system (Organisation for Economic Co-operation and Development [OECD] and the Food and Agriculture Organization of the United Nations [FAO] 2017). Finally, some environmental assessments look more closely at the interrelations between environmental issues and how they relate to human development. Examples include the Millennium Ecosystem Assessment (Millennium Ecosystem Assessment [MEA] 2005) and the United Nations Environment Programme's (UNEP) Global Environment Outlook reports (e.g. UNEP 2012).

Interestingly, a limited number of key archetypal scenarios, or scenario families, reappear in many of these assessments (van Vuuren *et al.* 2012). The term ‘scenario family’ denotes a set of scenarios in the literature that share a similar storyline or logic, resulting in a similar kind of quantification. Based on these key elements, van Vuuren *et al.* (2012) identified six scenario families:

- i. economic-technological optimism/conventional markets scenarios;
- ii. reformed market scenarios;
- iii. global sustainability scenarios;
- iv. regional competition/regional markets scenarios;
- v. regional sustainable development scenarios; and
- vi. business-as-usual or trend scenarios.

None of these scenarios is a prediction or forecast of the future. They are only meant to explore plausible future development pathways.

This chapter focuses on business-as-usual or trend scenarios. This type of scenario assumes that basic socioeconomic mechanisms continue to operate as they did in the past, and that no explicit new policies are introduced to meet specific policy targets. We assess the scenarios literature to analyse to what extent current and long-term trends are in line with achieving the environment-related targets of the SDGs and related MEAs (see selection of targets in Chapter 20), and to understand and highlight potential implementation gaps. The scenario assessment is used as a benchmark against which possible alternative future development pathways, that aim to achieve the selected targets simultaneously, are evaluated (see Chapter 22).

### Box 21.1: Waste as an important cause of environmental degradation

Part A of the sixth Global Environment Outlook (GEO-6) identified a number of consistent waste management issues of global concern, especially food waste and marine litter. It also pointed to a growing disparity across regions. Developed regions generate some 56 per cent of food waste, compared with 44 per cent in developing regions. Also, while developed regions increasingly invest in circular economy measures, about 3 billion people lack access to controlled waste disposal facilities, generating both health risks and environmental impacts. Plastic waste is of particular concern. However, there is a general lack of future waste flow studies, and such scenarios are mostly missing from the literature. Chapters 21 and 22 therefore do not discuss waste as a separate issue. Nevertheless, the problem of waste management is central to achieving several SDGs, and policies to address the growing waste problem will need to carefully consider both demand reduction and supply side restructuring.

## Box 21.2: The Shared Socioeconomic Pathways

21

The Shared Socioeconomic Pathways (SSPs) are five distinct global pathways describing the future evolution of key aspects of society that together imply a range of challenges for mitigating and adapting to climate change (O'Neill *et al.* 2017; Riahi *et al.* 2017). They have been developed into storylines and quantitative measures for a broad range of issues, including energy and land-use developments and related GHG emissions, based on scenarios and various other methods. As they are formulated relatively broadly and cover a wide range of possible futures, they are also used extensively for other fields of environmental research and assessment. The five SSPs are:

- i. sustainable development (SSP1);
- ii. the middle road (SSP2);
- iii. a fragmented world (SSP3);
- iv. inequality (SSP4); and
- v. fossil fuel-based development (SSP5).

The SSPs are not policy-free; they include all kinds of assumptions on policies. However, since they were formulated specifically to support climate change research and assessment, the reference scenario versions of the SSPs are free of climate policy beyond the base year.

The SSPs are certainly not free of environmental and sustainable development policies. In fact, key elements in SSP1, for instance, are low population growth, economic convergence, rapid technology development of environmentally friendly technologies and the introduction of environmental policies. By contrast, in SSP3 the fragmented world leads to high population growth, slow economic development and a focus on security issues; and thus, little priority for environmental issues.

## Box 21.3: The need for coordination among environmental assessments

There are currently several assessments that include an outlook component and focus on specific SDGs. These include the Global Biodiversity Outlook, the Global Land Outlook, the Intergovernmental Science-Policy Platform on Biodiversity and Ecosystem Services, and the Global Environment Outlook. As highlighted in the 2030 Agenda for Sustainable Development, it is clear that the SDGs cannot be achieved without taking into account important synergies and trade-offs across these goals (see also Section 22.4.2). For this reason, it will become increasingly important to coordinate the work across the various assessments, and check whether the key findings address the SDG agenda as a whole.

Not all relevant issues are addressed equally in the scenario literature. For instance, there are many scenarios published on climate change, while only a few scenario studies focus on water pollution. Other issues of global concern, such as chemicals and waste, are hardly addressed in the scenario literature (see Box 21.1). The available literature thus limits the scope of the analysis. As a result, not all relevant issues that are discussed in Part A of GEO-6, such as chemicals and waste, are covered in the analysis in Chapters 21 and 22.

A widely used set of scenarios are the Shared Socioeconomic Pathways (SSPs; see Box 21.2). The SSPs were developed principally to support climate research (van Vuuren *et al.* 2014; Riahi *et al.* 2017) but are also used extensively for other fields of environmental research and assessment. They explore a wide set of possible futures. Within the set, SSP2 is a scenario that represents medium developments for key drivers such as population, economic growth and technology development. Our assessment focuses on business-as-usual or trend scenarios, using the middle-of-the-road SSP2 scenario as a common thread across the different issues discussed. Other trend scenarios are used where relevant. Furthermore, SSP3 scenario results are shown where possible to indicate the risk of higher population growth.

### 21.3 The achievement of SDGs and related MEAs in trend scenarios

Business-as-usual or trend scenarios, as discussed in Section 21.2, are used to assess to what extent current and long-term trends are in line with achieving selected SDG targets (see Tables 20.1 and 20.2). Achievement of the selected targets is assessed in five distinct clusters of closely related environmental issues (see Figure 21.1). While interlinkages across these clusters exist, presenting them in these five clusters allows a more focused discussion. Four of the five clusters are closely related to the five environmental themes discussed in Part A (air, biodiversity, oceans, land and freshwater). Biodiversity and land are clustered together, as they are both strongly linked to developments in agriculture. In addition, human health is discussed as an individual cluster.

#### 21.3.1 Drivers

There are several key drivers of global environmental change. Here, we focus on population, urbanization and economic development. While climate change is discussed as a driver in Chapter 2, given that it cannot be influenced in the short term, it is assessed here as a global environmental challenge, as part of the energy, climate and air cluster. The role of technology is also discussed within the different clusters, primarily in the context of efficiency of resource use. It should be noted that (un)sustainable consumption and production practices also play a key role (see Section 2.5).

#### Population

The United Nations' World Population Prospects (United Nations 2017) and the population scenarios underlying the SSPs (Samir and Lutz 2017) are among those mainly used in the literature (see Section 2.2). The scenarios share important characteristics: they project population growth to continue and to reach a level of around 8.5 billion by 2030 and around 9-10 billion by 2050 (see Figure 21.2). The high population growth scenarios, such as SSP3, are typically associated with slow improvements in human development. Low population projections result from a relative rapid drop in fertility rates. More than half the anticipated growth is expected to occur in Africa and around 30 per cent in Asia (mainly South Asia). After 2050, Africa is projected to be the only region experiencing substantial population growth.

#### Urbanization

On a global scale, more people currently live in urban compared to rural areas (see Section 2.3). Urbanization levels differ significantly across world regions, with more than 80 per cent of the population living in urban areas in Latin America and the Caribbean, and only around 40 per cent in Africa. Urbanization is projected to increase in all regions, with average global urbanization levels growing to around 60 per cent in 2030 and 67 per cent in 2050 under the United Nations' World Urbanization prospects and SSP2 (United Nations 2014; Jiang and O'Neill 2017) (see Figure 21.2). Together with an increasing overall population, the global urban population is projected to grow by more than two-thirds between now and

Figure 21.2: Future projections of the global population (left) and urbanization (right)

Source: SSP projections (Jiang and O'Neill 2017; Samir and Lutz 2017); UN projections (United Nations 2014; United Nations 2017).

2050, with an increase of nearly 90 per cent in Africa and Asia (United Nations 2014). Under SSP3, assumptions on slow economic development coincide with a slower urbanization rate. Still, as total population growth is much higher, the urban population is projected to increase significantly.

### Economic development

In the past 30 years, the world economy grew on average by 3.5 per cent per year, a rate buoyed by strong economic growth in emerging economies in Asia (see Section 2.4). Most economic institutes only publish projections for the coming decade or shorter. In fact, most long-term economic projections are developed as part of environmental

Figure 21.3: Future projections of total GDP per region under SSP2 (left) and global GDP under SSP2 and SSP3 (right)

Source: Dellink et al. (2017).

assessments. The SSPs project the historic growth to continue, with around 3.1 per cent per year under SSP2 and 2.5 per cent under SSP3 (Dellink *et al.* 2017). For OECD countries, the projected economic growth is somewhat lower than the historical rate (1.7 per cent under SSP2), with annual growth declining over time due to ageing of the population. By contrast, low-income countries are projected to grow by around 3-5 per cent per year. Due to currently scarce capital inflows and high returns on capital investments, the potential for growth in labour and capital productivity is strong. For Asian countries, the projected growth rates are slightly lower than the rapid historical rates, further diminishing over time as a result of the maturing of their economies, with productivity levels approaching those of OECD countries. By contrast, growth rates are higher in Latin America and the Caribbean as well as Middle East and North Africa. While this implies that in relative terms there is some convergence between different parts of the world, the gaps remain significant. In terms of relative shares, these projections imply a strong shift. For instance, the OECD countries' current share of the global economy under SSP2 is projected to fall to less than one-third (compared with around one-half at present), while Asia's share is projected to grow to almost 50 per cent.

The economic projections also have implications for poverty. Historically, absolute poverty, as indicated by the number of people living on less than US\$1.90 a day, fell from 1.85 billion in 1990 to fewer than 800 million in 2013 (World Bank 2016a). Projections for 2030 range from 100 million to more than 1 billion, with most studies suggesting a level of 400 to 600 million people (Chandy, Ledlie and Penciakova 2013; Burt, Hughes and Milante 2014). The variation in the scenarios is due to the large differences in assumptions about growth in household consumption and changes in income distribution.

### 21.3.2 Agriculture, food, land and biodiversity

Food production and land use are directly related to a range of environmental problems (see Chapter 8). As population and incomes are projected to rise, food consumption, both per capita and total, is also expected to rise (Bijl *et al.* 2017; Popp *et al.* 2017). In 2050, estimated total crop production (food, feed and biofuels) ranges from 5,800 million tons per year to 8,300 million tons per year, an increase of 50 to 130 per cent from 2010 levels (Tilman *et al.* 2011; Popp *et al.* 2017), though most projections suggest an increase of 50 to 60 per cent.

Over the last decades, globally, about 80 per cent of the increase in food demand was met by agricultural intensification (increase in crop yields and move towards more intensified animal husbandry systems) and 20 per cent by an increase in agricultural area (Smith *et al.* 2010). These shares are projected to more or less continue into the future. The net result is an increase in total agricultural area (cropland and pasture) in 2050 of 3-9 per cent (Popp *et al.* 2017). Given that, in a number of regions the most productive lands have already been put to use, land expansion takes place on less productive land, requiring more area per ton of production (van der Esch *et al.* 2017). Overall, expansion comes at the expense of forests and savannahs, which are home to important biodiversity hotspots, carbon sinks and other ecosystem services (CBD 2014).

Overall, cereal yields are projected to increase by 0.4 to 0.9 per cent per year between 2010 and 2050 (Alexandratos and Bruinsma 2012; Popp *et al.* 2017), down from 1.9 per cent per year between 1961 and 2007 (Alexandratos and Bruinsma 2012). These future yield increases will be achieved through a combination of changes in fertilizer application, irrigation use and other means (e.g. mechanization, breeding), potentially increasing environmental pressures.

#### Box 21.4: Climate change impacts on agriculture

In the business-as-usual scenarios, global mean temperature is expected to increase to more than 2°C in 2050 and 2.5-6°C in 2100 (IPCC 2014b). For agriculture, such climate change is expected to pose significant risks by changing seasonal rainfall patterns, increasing peak temperatures, increasing the frequency and severity of droughts, increasing the risk of catastrophic events (storms) and disrupting ecosystem services to agriculture. This could clearly have a negative impact on the ability of the agricultural system to achieve the SDGs with respect to hunger, sustainable agriculture and protection of biodiversity. Projected impacts vary across crops and regions, and for different adaptation scenarios. In general, tropical regions are expected to experience more severe negative impacts than temperate regions – and they do so at lower levels of warming (in the historical period, stronger impacts in temperate regions have been reported according to IPCC). If adaptation to climate change is implemented, yields may increase, particularly in temperate regions, via the combined effect of climate change and CO<sub>2</sub> fertilization. According to the IPCC assessment, after 2050 there is a greater risk of more severe impacts. The combination of the growing demand for food and a temperature rise in the high end of the projections, implies substantial risks to food security at global and regional levels.

### Trends in hunger

A key challenge in this cluster is ending hunger by 2030 (SDG target 2.1). Between 2005 and 2014, global hunger has decreased, both in absolute and relative terms. However, since 2014 hunger has been on the rise, with an estimated 815 million people being undernourished in 2016 (FAO *et al.* 2017). Global models project a decrease in the undernourished population towards 2030, driven mostly by an expected income increase in current low-income regions (Alexandratos and Bruinsma 2012; Hasegawa *et al.* 2015; Laborde *et al.* 2016; Bijl *et al.* 2017; FAO *et al.* 2017). These projections are generally based on data from before 2014, and therefore do not include the recent rise in levels of hunger. Differences in historic hunger levels generally relate to the year that the model switches from historic data to model projections (here mostly 2005 or 2010). The number of undernourished people across the different studies is projected to be 300–650 million people in 2030 and around 100 to 300 million in 2050 (**Figure 21.5**). While this represents an improvement compared with today's figures, these levels significantly exceed the target of ending hunger by 2030.

**Figure 21.5: Future projections of global undernourished population**

Source: Alexandratos and Bruinsma 2012; FAO, International Fund for Agricultural Development and World Food Programme 2015; Hasegawa *et al.* 2015; Laborde *et al.* 2016; Bijl *et al.* 2017.

### Trends in biodiversity loss

As discussed in Chapter 6, biodiversity loss has a number of causes (SDG target 15.5). Most scenario studies have ascertained that natural habitat loss has been, and still is, the single most important factor causing biodiversity loss (Millennium Ecosystem Assessment 2005; Newbold *et al.* 2015). However, trends in water scarcity, climate change, pollution and disturbance all drive a further decline in biodiversity, while business-as-usual scenarios show that many of these factors are likely to worsen in the future (SCBD 2014; Kok *et al.* 2018). Climate change is projected to become a major cause of biodiversity loss, with species impacted by a range of factors including: temperature increase, altered precipitation patterns and rising sea levels. Climate change is also projected to alter the distribution of biomes over the coming century, with one-tenth to one-half

of global land being highly vulnerable to biome shifts under climate change (Gonzalez *et al.* 2010). Boreal forests may be particularly vulnerable (Gonzalez *et al.* 2010; Gauthier *et al.* 2015), but projections also show that 5–6 per cent of land area in Latin America could undergo biome shifts as a result of climate change by the end of the century (Boit *et al.* 2016). The combination of anthropogenic drivers could push some regional social-ecological systems beyond tipping points and transition them to states with severely reduced biodiversity and ecosystem services (Leadley *et al.* 2014).

Studies published after Global Biodiversity Outlook-4 provide further consensus that biodiversity will continue to decline under business-as-usual scenarios. Model projections suggest changes in a number of different dimensions of biodiversity. The Global Land Outlook provides projections of Mean Species Abundance (MSA), a measure of the intactness of ecosystems, projecting a further increase of MSA loss: from 34 per cent in 2010 to 43 and 46 per cent in 2050, under SSP2 and SSP3, respectively (van der Esch *et al.* 2017; **Figure 21.6**). Using scenarios of land-use change consistent with the IPCC's Representative Concentration Pathway (RCP) 8.5, Newbold *et al.* (2015) projected a fall of local species richness by 3.4 per cent by 2100 (**see Figure 21.6**). The combination of climate and land use change for the same RCP scenario is projected to lead to a cumulative loss of 38 per cent of species from vertebrate communities (Newbold 2018). Many of the effects are concentrated in biodiverse but economically disadvantaged countries (Newbold *et al.* 2015) and in tropical grasslands and savannahs (Newbold 2018). Furthermore, an extrapolation of the Living Planet Index (LPI), a measure of changes in

**Figure 21.6: Future projections of relative local species richness for a range of climate stabilisation scenarios and Mean Species Abundance (MSA) for SSP2 and SSP3 land-use**

Source: Relative species richness from Newbold *et al.* 2015; Mean species abundance from van der Esch *et al.* 2017

terrestrial, marine and freshwater vertebrate populations, suggests that by 2020 populations will have declined by 67 per cent, on average, compared to their 1970 population size (World Wide Fund for Nature [WWF] 2016). Population sizes of mammalian carnivores and ungulates are also projected to decline under future land use and climate change (Visconti *et al.* 2016). Declines of 18-35 per cent by 2050 were projected in a LPI-like index, based on species dispersal ability. These abundance declines are associated with an 8-23 per cent increase in the risk of extinction (Visconti *et al.* 2016).

### Trends in land degradation

Land degradation (SDG target 15.3) is a major problem worldwide, and is linked to food insecurity, vulnerability to climate change and poverty, as well as to mitigation of GHG emissions (UNCCD 2017; van der Esch *et al.* 2017). Estimates of the number of people affected by land degradation vary between a low range of 1.3-1.5 billion (Bai *et al.* 2008; Barbier and Hochard 2016; see Chapter 8) and much higher estimates of 3.2 billion (Intergovernmental Science-Policy Platform on Biodiversity and Ecosystem Services [IPBES] 2018). Although a significant proportion of those affected are poor rural inhabitants living on marginal lands, land degradation also occurs in prime agricultural lands due to mismanagement and/or overgrazing. For example, in Brazil, more than half of all pastures are in an advanced state of degradation, causing significant loss of productivity (Strassburg *et al.* 2014; Assad *et al.* 2015). In fact, expansion and unsustainable practices in agriculture and livestock production are the most important direct drivers of land degradation (IPBES 2018).

Globally, between 1982 and 2010, when correcting for climate effects, a declining trend in net primary productivity (NPP) is observed in about 12 per cent of agricultural land and in about 5 per cent of natural land (Schut *et al.* 2015; van der Esch *et al.* 2017). Regionally, the Russian Federation/Central Asia and

sub-Saharan Africa have about double the share of agricultural land with a declining NPP (Schut *et al.* 2015; van der Esch *et al.* 2017). Compared to an undisturbed state, current NPP is estimated to be significantly lower on 28 million km<sup>2</sup>, or 23 per cent, of the global terrestrial area, corresponding to about a 5 per cent loss in global NPP (Smith *et al.* 2016; van der Esch *et al.* 2017). Soil degradation involves, among other things, soil erosion and loss of soil organic carbon. Historically, around 176Gt of soil organic carbon (8 per cent) has already been lost as a result of land-use changes, including the conversion of natural land to agriculture, and overgrazing in grasslands (Stoorvogel *et al.* 2017a; Stoorvogel *et al.* 2017b). As a consequence of continued land conversion and unsustainable land management, an additional 27Gt of soil organic carbon is projected to be lost between 2010 and 2050, affecting agricultural yields through reduced water-holding capacity and loss of nutrients (van der Esch *et al.* 2017). Furthermore, losses in soil organic carbon will have wider effects on biodiversity, hydrology and carbon emissions. Further land degradation is expected to occur based on trends in land use (see Figure 21.4), climate change and increasing pressure on land and water resources. Land degradation is especially of concern in drylands, where, by 2050, human populations are projected to increase by 40 to 50 per cent under the SSP2 scenario, which is far greater than the 25 per cent increase projected for non-drylands (van der Esch *et al.* 2017). Overall, these trends show that without targeted policies, a land degradation neutral world will not be achieved.

### 21.3.3 Energy, air and climate

The energy system plays a crucial role in achieving sustainable development. The use of energy is a prerequisite for human welfare. At the same time, current energy consumption and production patterns contribute strongly to climate change and air pollution. In the next few decades, energy demand

**Figure 21.7: Future projections of global primary energy consumption (left panel) and per energy carrier in the SSP2 marker scenario (right panel)**

Source: SSP Public Database 2016; IEA 2017a; Riahi *et al.* 2017.

is expected to increase further, driven by population growth and related human activities. Overall, most scenarios project a 50-70 per cent increase in primary energy demand over the 2015-2050 period. This is despite a projected decrease in energy intensity of around 1-2.5 per cent per year, similar to that achieved historically (e.g. van Vuuren *et al.* 2016; Riahi *et al.* 2017). Although renewables are by far the fastest growing form of energy, fossil fuels continue to contribute the lion's share of total energy supply in scenarios without new policies. In most business-as-usual scenarios, the renewable energy share increases from 15 per cent in 2015 to around 20-30 per cent in 2050 (full range 10-30 per cent) (van Vuuren *et al.* 2016). Renewables started from a small share in 2015 and are mostly successful in replacing fossil fuels in the power sector, which constitutes an important but limited part of total energy consumption. Scenario studies specifically examining the impact of policies formulated by countries as part of their pledges under the Paris Agreement often have a somewhat lower energy demand and faster growth of non-fossil energy, but at best these result in a stabilization of fossil fuel demand.

### Trends in access to modern energy services

Access to modern energy services (SDG target 7.1) is an important prerequisite for human development (IEA 2017b). Currently, around 2.8 billion people worldwide rely on traditional biomass, kerosene and coal – fuels not considered to be clean – while 1.1 billion people do not have access to electricity (IEA 2017b). Exposure to household air pollution, caused by the use of traditional biomass in open fires or traditional stoves, can lead to child and adult mortality and morbidity. Overall, in 2015, household air pollution was responsible for almost 3 million deaths worldwide, including 250,000 child deaths (GBD 2016 SDG Collaborators 2017). Since 2000, progress has been made

in all regions, especially in Asia, while in sub-Saharan Africa population growth largely outpaced the progress made. These trends are projected to continue towards 2030 (Lucas *et al.* 2015; Dagnachew *et al.* 2017; IEA 2017b; Lucas, Dagnachew and Hof 2017). Overall, the population without access to clean cooking fuels is projected to decrease to around 2.3 billion people by 2030, with larger improvements in urban areas than in rural areas (IEA 2017b). Under SSP2 assumptions, by 2030 around 140,000 children under five per year are projected to die as a result of household air pollution (Lucas *et al.* 2018). Model projections also show a decline in the population without access to electricity to around 700 million in 2030, with most regions, except sub-Saharan Africa, reaching near universal access (IEA 2017b). Although between 2010 and 2030, more than 550 million additional people are projected to gain access to electricity in sub-Saharan Africa, 500 million people would still not have access in 2030, many of them living in rural areas (Dagnachew *et al.* 2017).

### Trends in climate change

Increasing fossil fuel use implies increasing greenhouse gas emissions and related global mean temperature (SDG 13). For the 2010-2050 period, GHG emissions are projected to increase by 30-70 per cent (Riahi *et al.* 2017; IEA 2017a; **Figure 21.8**). Most of this increase is projected for low-income countries. Nevertheless, per capita emissions remain highest in OECD countries. Emissions of greenhouse gases are not only expected to increase due to these energy-related trends; other activities are also expected to contribute. These include CO<sub>2</sub> emissions from land-use change (LUC) (slowly decreasing over time) and non-CO<sub>2</sub> emissions related to energy and agriculture. The sum of non-CO<sub>2</sub> emissions is expected to increase further over time, driven mostly by trends in agriculture.

**Figure 21.8: Projected increase in global CO<sub>2</sub> emissions (left) and total GHG emissions (right)**

Source: Results are shown for SSP2 (average across the different models elaborating this scenario and the lowest and highest in the range, Riahi *et al.* 2017) and SSP3 (model average; Riahi *et al.* 2017), as well as the IEA scenario (IEA 2017a, reference case).

As a result of this global emission increase, global temperature is expected to rise from around 1°C above pre-industrial levels in 2016 (Visser *et al.* 2018) to around 4°C by 2100 in SSP2, most likely passing the 2°C target of the Paris Agreement before 2050 (IPCC 2014b; see **Figure 21.9**). There are substantial differences in temperature increase across different areas of the world. Typically, temperature increase is greater at higher latitudes, such as the temperate zone and in polar regions. In addition to changes in temperature, considerable changes in precipitation are projected to occur, with some regions becoming drier and others becoming wetter. However, such detailed patterns in climate change variables are still very uncertain. In many places, the projected warming would exceed the global mean temperature increase (which is defined as the increase in temperature above land and oceans). Using projected changes in temperature, the IPCC has assessed the impacts associated with climate change (IPCC 2014b). For a warming as high as in the business-as-usual scenarios projected here the impacts are assessed to be severe, for all categories. This includes sea level rise, negative impacts on agriculture globally (see **Box 21.4**), negative impacts on biodiversity, and the risk of irreversible changes in the complete climate system.

### Trends in air pollution

From the public health perspective, airborne particles and ground level ozone are the most important air pollutants (SDG target 11.6), with exposure to PM<sub>2.5</sub> contributing the most

to premature deaths (see Chapter 5). The Global Burden of Disease study estimated that exposure to ambient PM<sub>2.5</sub> was the fifth-ranking mortality risk factor in 2015, contributing to approximately 4 million deaths and 103 million years of healthy life lost (Cohen *et al.* 2017).

Several projections of future air pollution have been made over the past few years (Stohl *et al.* 2015; IEA 2016; OECD 2016; Klimont *et al.* 2017; Rao *et al.* 2017; UNEP 2017). Many projections have been built using emission factors from successive versions of the Greenhouse Gas and Air Pollution Interactions and Synergies (GAINS) model (Amann *et al.* 2011; Klimont *et al.* 2017). In addition to the evolution of these underlying emission factors, future projections differ in their assumptions about energy supply and demand, and the extent to which air pollution control policies will be implemented in the future.

The most pessimistic scenarios examine a situation in which no additional air pollution control policies are implemented. An example is the OECD (2016) study, that projects a significant increase in air pollution emissions by 2060 due to increasing economic activity and energy demand. More realistic scenarios look into expected improvement in air pollution legislation. For instance, the IEA-New Policies Scenario (IEA 2016) projects a more optimistic future in which recently announced policies, including Nationally Determined Contributions (NDCs), under the Paris Agreement, are implemented, leading to the use of emission control technologies and facilitating a shift to cleaner energy sources. These new policies will lead to a slow decline in global air pollutant emissions by 2040, although rapidly developing regions are likely to continue to experience increases in air pollution emissions (IEA 2016; UNEP 2017). In high-income countries, emission decreases are expected as a result of increasingly stringent air pollutant emission standards on power plants and vehicles, shifts to low-carbon sources for electricity generation, and increased energy efficiency. In developing regions, the growth in economic activity and energy demand is still expected to outpace efforts on pollution control until income level reaches a certain point. However, PM<sub>2.5</sub> emissions (primarily organic carbon (OC) and black carbon (BC)) and exposures may decline due to increased access to clean energy sources for cooking, heating and lighting (IEA 2016). The ECLIPSE project (Stohl *et al.* 2015; Klimont *et al.* 2017), which has been used more broadly by the atmospheric research community, e.g. the 2017 Emissions Gap Report (UNEP 2017), includes a current legislation (CLE) scenario that falls between the OECD and IEA pathways. Air pollution emissions scenarios were developed for each of the SSPs based on sets of assumptions about the stringency and implementation of future air pollution emissions controls consistent with the overall scenario storylines (Rao *et al.* 2017). These scenarios also used the emission factors of the GAINS model. To 2040, the range of the SSP air pollutant emission scenarios captures the more pessimistic scenarios of continued growth without additional policies (OECD 2016) and the more optimistic scenarios of new policies (IEA 2016).

Figure 21.10: Future projections of emissions for air pollutants SO<sub>2</sub>, NO<sub>x</sub> and BC

Source: ECLIPSE\_V5\_NFC and ECLIPSE\_V5a\_CLE represent ECLIPSE's 'no further control' and 'current legislation' scenarios (Stohl *et al.* 2015; Klimont *et al.* 2017). IEA New Policies represent IEA's new policy scenario that includes NDCs of the Paris Agreement (IEA 2016). For the SSP2 scenario, the shading represents the range for all models (Rao *et al.* 2017).

Overall, scenarios without new policies show a small decrease or increase in air pollutant emissions. Based on data from the Global Burden of Disease (GBD 2016 Risk Factors Collaborators 2017), in 2016 approximately 95 per cent and 58 per cent of the world's population lived in areas where annual mean PM<sub>2.5</sub> concentrations exceeded the 10µg/m<sup>3</sup> guideline and the least stringent interim target of 35µg/m<sup>3</sup>, respectively, contributing to approximately 4 million premature deaths (Health Effects Institute 2018). Using emissions data as input, the TM5-FASST source-receptor model (van Dingenen *et al.* 2018) can be used to estimate annual PM<sub>2.5</sub> concentrations, which can be mapped onto future population projections to estimate those exposed to specific PM<sub>2.5</sub> levels and the number of premature deaths. By 2050, the projected values for populations exposed to PM<sub>2.5</sub> concentrations above 10µg/m<sup>3</sup> and 35µg/m<sup>3</sup> are 63 and 9 per cent, respectively, for the SSP2 marker scenario (Rao *et al.* 2017), and 81 and 40 per cent, respectively, for the ECLIPSE V5a 'current legislation' scenario (Stohl *et al.* 2015; Klimont *et al.* 2017). This implies that air pollution will continue to contribute to millions of premature deaths annually, with the IEA New Policies scenario estimate of 4.5 million premature deaths for 2040 (IEA 2016), and the ECLIPSE V5a scenario estimate of 7 million premature deaths for 2050 (Stohl *et al.* 2015; Klimont *et al.* 2017) spanning the range in the literature. Global economic losses due to decreased labour productivity, increased health care costs and decreased crop yields could amount to 1 per cent of global gross domestic product (GDP) by 2060 (OECD 2016). There are large differences across regions, with some experiencing as much as 3 per cent loss in GDP (OECD 2016).

#### 21.3.4 Freshwater

Freshwater - related environmental problems are closely linked to developments in the agriculture, food, land and biodiversity cluster (see Section 21.3.2) and the energy, air and climate cluster (see Section 21.3.3), both as a natural resource and as a sink for pollution. Freshwater is essential for human health (drinking water and sanitation), as well as for agriculture and energy production, while an imbalance of freshwater supply and demand can cause severe water scarcity. Furthermore, excess nutrient losses (nitrogen and phosphorus) to aquatic ecosystems through run-off and erosion can cause the eutrophication of lakes and rivers.

##### Trends in drinking water and sanitation

In 2015, nearly 2.1 billion people lacked access to safely managed drinking water services (SDG target 6.1), while 0.8 billion of these even lacked an improved source (World Health Organization [WHO] and United Nations Children's Fund [UNICEF] 2017). Furthermore, 4.5 billion people lacked access to safely managed sanitation services (SDG target 6.2), while 2.3 billion of these even lacked an improved source (WHO and UNICEF 2017). Overall, unsafe drinking water, sanitation and hand washing (WASH) were responsible for around 1.5 million deaths, including 410,000 child deaths, mainly due to diarrheal diseases (GBD 2016 SDG Collaborators 2017). Lucas *et al.* (2018) project that, by 2030, more than 30 million children will still live without access to improved drinking water services, and about 150 million will lack access to improved sanitation, under SSP2 assumptions. This translates into 400

million people that live without access to improved drinking water services and about 2 billion without access to improved sanitation. Especially the sanitation challenge is a pressing one. Between 2015 and 2030, around 5.6 billion people will require safely managed sanitation and around 1.3 billion people will need to switch from open to fixed point defecation (Mara and Evans 2018). Improved access to safely managed WASH would lead to a significant reduction in the number of children suffering from related ill health. However, under SSP2 assumptions, by 2030 around 220,000 children under five are projected to die as the result of inadequate drinking water and sanitation facilities (Lucas *et al.* 2018).

### **Trends in water quality**

Freshwater pollution includes different types of chemicals, but also excessive nutrient loading (nitrogen and phosphorus) of aquatic ecosystems through run-off and erosion and declining silica concentrations. Since scenario studies related to chemicals are largely missing from the scientific literature (see Box 21.3), the analysis of trends for this target focuses on nutrient pollution.

Nitrogen (N) and phosphorus (P) fertilizers have played a major role in food production, but they have also found their way into nearly every water body across the globe, causing eutrophication of rivers, lakes and reservoirs (SDG target 6.3). The most important anthropogenic source of nitrogen in freshwater ecosystems is agriculture-related N-fixation (nitrogen fertilizer use and biological crop fixation). For phosphorus, the main anthropogenic sources are phosphorus fertilizer use and wastewater. Current agricultural N-fixation is estimated at 116-127TgN/yr (Bouwman *et al.* 2017). Alexandratos and Bruinsma (2012) project an increase of synthetic N use to 138TgN/yr in 2050, while Mogollón *et al.* (2018a) project an increase to 185 and 260TgN/yr in 2050 under an SSP2 and SSP3 scenario, respectively, illustrating the uncertainty in future projections. Global phosphorus inputs to cropland are projected to increase from 14.5TgP/yr in 2010 (Bouwman *et al.* 2017) to 26 and 27TgP/yr in 2050 under an SSP2 and SSP3 scenario, respectively (Mogollón *et al.* 2018b).

Future projections of N fertilizer use depend strongly on developments in N use efficiency (NUE), which declined from 0.42 in 1970 to 0.35 in the 1980s and then increased again to 0.42 in 2010 (Bouwman *et al.* 2017). The decreasing trend in the 1980s was due to increasing fertilizer use in low-input countries, which initially led to an apparent decline in efficiency, while the later increase was largely the result of improvement in agricultural practices and environmental legislation in developed regions (Bouwman *et al.* 2017; Rao *et al.* 2017). These trends are projected to continue in the future, with projected NUE for SSP2 increasing to 0.55 in 2050 (Mogollón *et al.* 2018a). The P use efficiency (PUE) declined from 0.51 in 1970 to somewhat lower values in the 1980s, and then to 0.6 in 2010 (Mogollón *et al.* 2018b). Future PUE values depend strongly on phosphorus accumulation (low PUE) in residual soil pools or their depletion (high PUE), which can be regarded as a contribution to future production.

It is clear that current and projected nitrogen and phosphorus use in agriculture significantly exceeds the target levels of 62TgN/yr and 6.2TgP/yr. At the same time, construction of dams and the development of reservoirs for water storage and hydropower generation leads to trapping of silica (Si)

(e.g. Mavaara, Dürr and van Cappellen 2014; Ran *et al.* 2018). The distortion of the nutrient stoichiometry (increasing N:P, increasing N:Si) may lead to the proliferation of harmful algae. The global problem of harmful algae is now on a pathway of more and more frequent blooms, in more places with an increasing extent, and with more toxins (Glibert 2017).

Wastewater is another important source of nutrients in freshwater systems. Improved sanitation is focused on health aspects, and sanitation systems are designed to hygienically separate excreta from human contact. However, without wastewater treatment, sewage systems create direct emissions of nutrients and organic waste to surface water (van Puijenbroek *et al.* 2015). Although access to sanitation is projected to increase, expansion of wastewater treatment will be outpaced by population growth and urbanization trends in developing countries (van Puijenbroek, Beusen and Bouwman 2019). As a result, global nutrient emissions from untreated sewage are projected to increase from 10TgN/yr in 2010 to 17TgN/yr in 2050, and from 1.5TgP to 2.4TgP under SSP2 assumptions (van Puijenbroek, Beusen and Bouwman 2019).

### **Trends in water scarcity**

At present, more than 2 billion people across the globe live in river basins with excess water stress (SDG target 6.4), i.e. the proportion of total freshwater withdrawal to total renewable freshwater above a threshold of 40 per cent (Oki and Kanae 2006; Veldkamp *et al.* 2015; Liu *et al.* 2017). In some countries in Africa and Asia, the proportion extends beyond 70 per cent (Economic and Social Council 2017).

Global human water demand, i.e. water withdrawal, is projected to increase under all trend scenarios. Some scenarios show quite large increases, i.e. from around 4,000km<sup>3</sup> yr<sup>-1</sup> now to 5,500km<sup>3</sup> yr<sup>-1</sup> by 2050 (38 per cent) under SSP2 (Wada *et al.* 2016; Satoh *et al.* 2017). Others show a smaller increase, based on expected efficiency improvements. For instance, Bijl *et al.* (2018) project a 26 per cent increase in total water demand by 2050 under an SSP2 scenario. For the high demand scenario, consumptive water use is projected to increase from 2,000km<sup>3</sup> yr<sup>-1</sup> now to 2,500km<sup>3</sup> yr<sup>-1</sup> by 2050 (25 per cent) under SSP2 (Wada and Bierkens 2014). An additional 10 per cent increase of water use is expected under SSP3 (Wada *et al.* 2016).

Improvement in water-use efficiency is expected to vary for different sectors (agriculture, industry and households), and ranges between 0.3 and 1.0 per cent per year under the SSP scenario, which mostly follows historical development (Flörke *et al.* 2013; Wada *et al.* 2016). Furthermore, the efficiency improvement is expected to vary substantially across different regions, depending on available infrastructure and economic investments. The greatest increases in total water demand are expected in Africa, many parts of Asia, the western United States of America, Mexico, and Latin America (Hanasaki *et al.* 2013a; Hanasaki *et al.* 2013b; Wada *et al.* 2016) and will largely be the result of rapidly growing population and increasing industrial activities (higher electricity and energy use) in currently developing countries (Hanasaki *et al.* 2013a; Hanasaki *et al.* 2013b; Bijl *et al.* 2016; Wada *et al.* 2016; Satoh *et al.* 2017).

Increases in future agricultural water demand are primarily driven by the expansion of irrigated areas and projected climate change, which enhances evaporative demand for irrigated crops (Hanasaki *et al.* 2013a; Hanasaki *et al.* 2013b; Wada and

Bierkens 2014; Mouratiadou *et al.* 2016). Compared with the domestic and industrial sector, the projected irrigation water demand shows a much lower increase of 20 to 30 per cent by the end of this century (Elliot *et al.* 2014), although some project a doubling of irrigation water withdrawals between 2010 and 2050 (Chaturvedi *et al.* 2015). Although modest changes in global average irrigation efficiency are projected (Hanasaki *et al.* 2013a; Hanasaki *et al.* 2013b), this will probably compensate for the increase in irrigated areas and irrigation intensity (Wada *et al.* 2013), with significant differences in efficiencies across regions (Chaturvedi *et al.* 2015). It should be noted that increasing atmospheric CO<sub>2</sub> concentrations can improve crop growth and reduce crop transpiration, while simultaneously, increased biomass use could potentially offset the gains in crop transpiration (Wada *et al.* 2013).

The trends under both medium and high water demand scenarios (SSP2 and SSP3) imply that water scarcity is expected to increase. For instance, studies project a large increase in water scarcity over 74 to 86 per cent of the total area of Asia under different SSP scenarios, and that at least 20 per cent of the area will probably be subject to severe water stress by the 2050s in Asia (Wada and Bierkens 2014; Satoh *et al.* 2017). It is important to note that a severe reduction in water resources is expected in many parts of arid and semi-arid regions due to climate change (Schewe *et al.* 2014). At present, more than 1 billion people in Asia live in regions with severe water stress, totalling almost one-third of the Asian population (Liu *et al.* 2017). By 2050, the Asian population exposed to severe water stress conditions is expected to increase by 42 to 75 per cent, depending on which scenario is considered (SSP1-3), potentially extending to 2 billion people under the SSP3 high water demand scenario (Satoh *et al.* 2017). Globally, the number of people living in a severe water stress areas show a similar trend, increasing from 2 billion people now to between 2.8 and 3.4 billion people by 2030, under the SSP2 and SSP3 scenarios, respectively (Hanasaki *et al.* 2013a; Hanasaki *et al.* 2013b). Increased water stress can damage renewable freshwater resources to the point where they are unable to sustain human activities and fulfil their ecological functions (Satoh *et al.* 2017; Greve *et al.* 2018). The consequences of water stress also affect agriculture, health and income. Studies show that water stress could lead to a 7-10 per cent reduction in GDP in Central and East Asia by 2050 (World Bank 2016b; Satoh *et al.* 2017).

At the same time, the amount of non-renewable groundwater abstraction is projected to double for almost all major groundwater users under the SSP2 and SSP3 scenarios. The share of non-renewable to total groundwater abstraction is expected to increase from 30 to 40 per cent, indicating a growing reliance of human water use on non-renewable groundwater resources (Elliot *et al.* 2014; Wada and Bierkens 2014). In some areas, the groundwater table may drop too deep, or the aquifer or river may run out of water, increasing concern for food security, energy, cities and ecosystems (Vanham *et al.* 2018).

### 21.3.5 Oceans

Ocean - related environmental problems are closely linked to developments in the agriculture, food, land and biodiversity cluster (see Section 21.3.2) and the energy, air and climate cluster (see Section 21.3.3), both as a natural resource and as a sink for pollution. Oceans are an important source of food and nutrition for billions of people, and although not discussed in the current section, they are also important for renewable energy, including offshore wind farms and tidal energy. With respect to pollution, excess nitrogen and phosphorus loadings associated with anthropogenic activities, including agriculture and sewage, can cause dead zones and toxic algae blooms in inland and coastal waters, while increasing CO<sub>2</sub> emissions, mostly generated by the energy system, exacerbate ocean acidification.

#### **Trends in marine nutrient pollution**

Major threats from nutrient enrichment and changing nutrient ratios are the development of dead zones and toxic algae blooms in inland and coastal waters. The Si:N and Si:P ratios in rivers have declined steadily during the past century (Billen, Lancelot and Meybeck 1991). This is due to elevated N and P loadings associated with anthropogenic activities (Beusen *et al.* 2016), while dissolved Si supply to rivers (primarily from rock weathering) is decreasing due to enhanced Si retention in reservoirs (Conley 2002). As a result community structures change, since siliceous algae (diatoms) require Si in balance with N and P (Si:N ≈ 1; Si:P ≈ 16). Threats from marine nutrient pollution (SDG target 14.1) occur when N and P are present in excess relative to Si, and phytoplankton communities are dominated by non-diatoms and often toxic algae and cyanobacteria proliferate (Anderson, Glibert and Burkholder 2002).

Global river N export estimates range from 37Tg N/yr (Beusen *et al.* 2016) to 43Tg N/yr (Seitzinger *et al.* 2010) for the year 2000. For global river P export estimates range from 4TgN/yr (Beusen *et al.* 2016) to 9Tg N/yr (Seitzinger *et al.* 2010). Increasing inputs from agriculture and wastewater are projected to result in an increase of the global river nitrogen export from 40Tg N/yr in 2006 to 47Tg N/yr in 2050, while P exports are projected to increase from 4Tg P/yr in 2006 (based on Beusen *et al.* 2016) to 5Tg P/yr in 2050, according to the SSP2 scenario (Ligtvoet *et al.* 2018). Although there are considerable uncertainties in historic estimates of phosphorus flow from freshwater systems into the ocean, future trends are moving in the wrong direction.

#### **Trends in ocean acidification**

Increases in CO<sub>2</sub> concentrations result in increased ocean acidity (SDG target 14.3) and decreased ocean productivity. Under a high emissions scenario (RCP 8.5) the global average ocean acidity level (pH) is projected to decline by approximately 0.2 in 2060 (Palter *et al.* 2018) and by 0.33 in 2090 (Bopp *et al.* 2013), compared with the 1990s. Lower pH levels (higher acidity) reduce the concentration of carbonate ions, which are required by marine organisms to create shells and skeletons. Higher acidity means that the global average calcium carbonate (CaCO<sub>3</sub>) saturation state of seawater with respect to aragonite (a type of CaCO<sub>3</sub> produced by marine organisms, the saturation state of which is denoted: Ω<sub>arg</sub>) in the upper water column would decline to levels that are significantly below the selected target level of 2.75Ω<sub>arg</sub> – from 2.94Ω<sub>arg</sub> in 2010 to around 1.8Ω<sub>arg</sub> in 2100 (Zheng and Cao

2014). Declines in carbonate saturation state make it more difficult for marine organisms to form shells and skeletons, can lead to their dissolution, and may increase natural mortality or decrease somatic growth and egg viability (Cattano *et al.* 2018). Regionally, acidification is expected to increase most rapidly in polar areas, with carbonate ion concentrations projected to fall below aragonite saturation levels in the Arctic Ocean beginning in 2048, and in the Southern Ocean in around 2067 (Bopp *et al.* 2013; Ciais *et al.* 2013). It should be noted that nitrogen and phosphorus run-off into the ocean from agriculture and industrial sources can lead to locally enhanced ocean acidification (Billé *et al.* 2013).

### **Trends in ocean resources**

Protecting ocean resources (SDG target 14.4) is critical, as oceans are sources of food and nutrition for billions of people, especially in income-poor coastal zones where significant shares of nutrition and income derive from fisheries. In addition to being a direct source of human food, fish also contribute indirectly to human nutrition when used as fishmeal in aquaculture and livestock feed. Historically, fish demand per capita has risen significantly from 6kg/yr in 1950 to 20.3kg/yr in 2016 (FAO 2018), with other estimates spanning the range 18.8-21.4kg/yr in 2011 (Troell *et al.* 2014; Béné *et al.* 2015). At the same time, there has been a trend towards farmed fish. Since 2014, humans have consumed more farmed fish than wild fish (FAO 2016). Projections from FAO suggest that demand for fish will continue to grow in the future (FAO 2018). However, studies indicate that a sustainable increase in wild fish catch will be difficult under current fishing strategies (Garcia, Rice and Charles 2016; FAO 2018). One important concern is that projections of marine primary productivity, which supports all marine fisheries, and ultimately all marine life, suggest a decline to 2100 under an RCP 8.5 scenario (Bopp *et al.* 2013; Fu, Randerson and Moore 2016), although considerable uncertainties remain (Laufkötter *et al.* 2015). No projections of the 'proportion of fish stocks within biologically sustainable levels' – the official SDG indicator – are available in the literature. As a proxy, projections of global fisheries under an unchanged climate and current management scenario, suggest that, the proportion of fish stocks at or below a target biomass that can undergo recovery would increase from 53 per cent today to 88 per cent in 2050 (Costello *et al.* 2016). However, a wide range of improved management measures already in place. In most countries that are funding science and management adequately (Melnichuk *et al.* 2017), significantly improve the prospects for sustainability (Costello *et al.* 2016). Catch potential is projected to decline by an average of 7.7 per cent by 2050, while revenue might decline by 10.4 per cent over the same period (Lam *et al.* 2016).

### **21.3.6 Human health**

In 2012, 23 per cent of deaths globally were due to modifiable environmental factors – “those reasonably amenable to management or change given current knowledge and technology, resources, and social acceptability,” (Prüss-Üstün *et al.* 2016) – with a greater portion occurring in vulnerable populations (children and the elderly) and developing countries (Prüss-Üstün *et al.* 2016). The environment affects human health within households (e.g. through unsafe water, sanitation and hygiene, and indoor air pollution), in communities (e.g. outdoor air pollution), and on a global scale (e.g. climate change) (Smith and Ezzati 2005; Hughes *et al.* 2011).

The proportion of the population with access to safe water, sanitation, and hygiene facilities, as well as clean cooking facilities has been increasing significantly reducing health impacts related to communicable diseases. These trends are projected to continue to 2050 (see Sections 21.3.3 and 21.3.4). For example, global Disability Adjusted Life Years (DALYs), the number of years lost to poor health or early death related to household air pollution due to use of solid fuels, decreased from 9.2 per cent of total DALYs in 1990 to 6.8 per cent in 2016 (Institute for Health Metrics and Evaluation 2016), and is projected to further decline to under 3 per cent by 2024 (Kuhn *et al.* 2016). Hughes *et al.* (2011) also project significant decreases in mortality from communicable diseases, largely related to strong economic development. However, many people are projected to live without proper access to improved drinking water and sanitation and clean cooking facilities by 2030, and the levels of improvement across these risk factors vary widely by region. Furthermore, health risks associated with outdoor air pollution and climate change have been increasing (WHO 2014; Forouzanfar *et al.* 2015; Cohen *et al.* 2017). The impact from ambient particulate matter pollution will continue to contribute to millions of premature deaths annually in the coming decades (see Section 21.3.3). Likewise, climate change is projected to have substantial negative health impacts in the coming decades, among them heat exposure, coastal flooding, diarrhoea, malaria and undernutrition (Hughes *et al.* 2011; WHO 2014).

Environmental risk factors at household level have been declining since 1990, while risk factors at community and global level have been increasing. Global health risks have been shifting away from environmental risks and towards behavioural risks (e.g. smoking, childhood undernutrition, and alcohol use) and metabolic risks (e.g. high blood pressure, and high body mass index) (WHO 2009; Forouzanfar *et al.* 2015). This shift in risk factors is part of a larger epidemiological transition, which has occurred globally over the past two centuries – mortality rates have been decreasing and shifting towards risks that affect people later in life (Murray *et al.* 2015).

### **Trends in child mortality**

Under-five mortality is generally seen as a good indicator of quality of life (see Section 20.4.1). Global child mortality (SDG target 3.2) declined dramatically from 91 deaths per thousand live births in 1990 to 43 per thousand live births in 2015, one of the most successful achievements of the Millennium Development Goal period (You *et al.* 2015). Yet more than 5 million children died in 2016 before reaching their fifth birthday, and 26 per cent of these deaths were due to environmental factors within our control (Prüss-Üstün *et al.* 2016). The five leading environmental risk factors (in order of health impact) are: household air pollution, unsafe drinking water, ambient particulate matter, unsafe sanitation, and insufficient handwashing (WHO 2009; Forouzanfar *et al.* 2015). Furthermore, malnutrition, including fetal growth restriction, child stunting and wasting, micronutrient deficiencies and suboptimal breastfeeding are important health risk factors, related to about 45 per cent of child deaths in 2011 (Black *et al.* 2013). In 1990, these five leading environmental factors accounted for nearly 2.8 million deaths in children under five (30 per cent of total under-five deaths), which decreased to just over 800,000 deaths in 2016 (24 per cent of total under-5 deaths). Currently, 79 countries have under-five mortality rates higher than the SDG target of 25 per 1,000 live births –

Figure 21.11: Projected under-five mortality rate in 2030

Source: Moyer and Hedden (2018).

partly due to persistent and sometimes even increasing environmental risk factors in low- and middle-income countries (GBD 2015 SDG Collaborators 2016).

Global child mortality is projected to decrease further to around 23 to 39 deaths per thousand live births by 2030, which is not enough to achieve the SDG target (Hughes *et al.* 2011; Liu *et al.* 2015; You *et al.* 2015; GBD 2016 SDG Collaborators 2017). This means that an estimated 47 countries are not on track to achieve the target by 2030, mostly in sub-Saharan Africa (You *et al.* 2015). As a result of decreasing child mortality, global average life expectancy at birth is projected to increase to over 77 by 2050, compared with 71 in 2015 (Samir and Lutz 2017; United Nations 2017). It should be noted that average figures such as these conceal huge differences in life expectancy, especially related to differences in poverty within and across countries.

Child mortality, especially from diarrhoea and pneumonia, is expected to decrease significantly, due to projected improvements in hunger levels (see Sections 21.3.2), access to modern sources of energy (see Section 21.3.3), and access to clean drinking water and sanitation (see Section 21.3.4), as well as to improved overall development levels (Lucas *et al.* 2018). However, by 2030, the five leading environmental risk factors, together with child underweight and malaria, are nevertheless projected to contribute to around 15 per cent of total child deaths, with a greater portion in sub-Saharan Africa (Lucas *et al.* 2018). These health impacts are largely preventable, but require interventions aimed at ensuring cleaner and sustainable access to food, water and energy services. Furthermore, climate change can exacerbate child mortality risks, for example, through impacts on food security and consequent levels of child underweight. Including climate change impacts on child underweight in their base case scenario projection,

Hughes *et al.* (2011) project 70,000 additional child deaths in 2050, mostly in southern Asia and sub-Saharan Africa.

It should be noted that household, community and global environmental factors affect many human development indicators beyond child mortality and, in turn, that child mortality is affected by many factors other than modifiable environmental factors. As indicated above, the epidemiological transition implies a change in the balance of risks attributable to the environment, e.g. from water - related communicable diseases, to non-communicable diseases related to, for example, ambient air pollution. Success in dealing with the first of these will show far greater benefits for under-five mortality than success in dealing with the second. Furthermore, other environmental health risk factors affecting health in the under-fives – undernourishment for some, obesity for others – may show as increased risks to health and mortality in later life, rather than (or in addition to) mortality in the under-fives.

## Box 21.5: Country level achievement of selected SDG targets

21

The 2030 Agenda is a global agenda, to be implemented at national level. This chapter explicitly evaluates future developments of selected environment-related SDG targets at a global level. The analysis concludes that without enhanced policies, the targets are unlikely to be met. However, the level of success differs largely across countries. Moyer and Hedden (2018) explored future country level progress under a SSP2 scenario, for eight SDG targets and nine related indicators. These targets link to selected SDG targets for the human well-being cluster, supplemented by SDG targets addressing poverty eradication and education. The nine indicators, though not comprehensive, represent multiple dimensions of human development.

In line with conclusions in this chapter (see Table 21.2), the study concludes that between 2015 and 2030, the world will make only marginal progress towards achieving the nine SDG indicators. On all country indicator combinations explored (nine indicators for 186 countries = 1,674 indicator values in each year), 43 per cent had already achieved target values in 2015, which is projected to increase to 53 per cent in 2030. Only 17 per cent of the countries are projected to achieve all SDG targets analysed by 2030, while 15 per cent of the countries do not achieve any of the selected SDG targets. Most of these latter countries are in sub-Saharan Africa. The analysis highlights difficulty in achieving target values for access to sanitation, universal lower secondary education and reducing the prevalence of underweight children, representing persistent development issues. The child mortality SDG target is projected to be achieved by 67 per cent of countries in 2030, while only 8 per cent achieve this target in sub-Saharan Africa.

## 21.4 Are we achieving the targets?

The results of the scenario assessment are summarized in **Table 21.2** with reference to the selected SDG targets and indicators (see Chapter 20). None of these targets is assessed to be achieved in the business-as-usual scenarios examined, but clear differences exist.

For the targets grouped under human well-being, the projected trends show improvements over time, but not sufficient to achieve them by 2030. However, several targets are projected

to be achieved in the longer term, or at least come relatively close to being achieved; for instance, the prevalence of undernourishment is projected to be reduced by two-thirds or more in 2050. While progress is sufficiently rapid to compensate for the growing world population, many people will nevertheless be left without proper access to food, modern energy services or adequate drinking water and sanitation. Linked to this, environmentally related human health impacts are decreasing significantly, but far from enough to achieve the SDG target on under-five mortality. Environmental health risk factors remain especially prominent in sub-Saharan Africa.

**Table 21.2: Past and future trends related to selected targets (see Section 20.4)**

| Cluster               | Selected target for GEO-6                                       | Indicator                                                                                           | 2010 Level                      | Target value                             | Projected value <sup>1</sup>               | Trend |

↗️ Target projected not to be achieved; trend in opposite direction or no significant improvement;

⬇️ Target projected not to be achieved; trend in right direction;

⬆️ Target projected to be achieved (none).

Source: All values are based on Section 21.3. <sup>1</sup> Projected values are mostly for SSP2 scenarios, except for energy access, under five mortality rate, ocean acidification and fish stocks above target biomass. For air pollution, results of the ECLIPSE scenario are also included due to the large uncertainty range.

For the targets grouped under natural resource base, the gap remains relatively large, and for most targets they even become wider. Although resource use efficiency (in terms of yield and nutrient use, water and energy efficiency) is projected to improve, mostly in line with historical trends (see **Table 21.3**), trends in climate change, biodiversity loss, water scarcity, nutrient pollution and land degradation are projected to continue to move in the wrong direction. Only the proportion of the population exposed to  $PM_{2.5}$  concentrations above  $35\mu g/m^3$  is projected to decrease. Still, under a SSP2 scenario, 63 per cent of the population is projected to be exposed to  $PM_{2.5}$  above  $10\mu g/m^3$  by 2050, concluding that air pollution will continue to contribute to millions of premature deaths in the coming decades.

Overall, the scenario analysis shows that the world is not on track to achieve selected environment - related targets of the SDGs and related MEAs. A significant increase in the rate of improvement with respect to reducing child mortality, air pollution control, hunger eradication and achieving access to clean water, sanitation and modern sources of energy is required. Furthermore, achieving the targets that address the natural resource base, including on climate change, biodiversity loss, land degradation, water scarcity and pollution of freshwater and oceans, requires a clear break with current trends, with absolute decoupling of human development from environmental degradation.

**Table 21.3: Historic and business-as-usual trends in resource use efficiency sustainable consumption and production**

# Chapter 22

## Pathways Toward Sustainable Development

**Coordinating Lead Authors:** Detlef van Vuuren (PBL Netherlands Environmental Assessment Agency), Paul Lucas (PBL Netherlands Environmental Assessment Agency)

**Lead Authors:** Katherine V. Calvin (Joint Global Change Research Institute/ Pacific Northwest National Laboratory), Serena H. Chung (United States Environmental Protection Agency), Mike Harfoot (World Conservation Monitoring Centre [UNEP-WCMC]), Steve Hedden (Frederick S. Pardee Center for International Futures), Alexandre C. Köberle (Universidade Federal do Rio de Janeiro), Yoshihide Wada (International Institute for Applied Systems Analysis)

**Contributing Authors:** Lex Bouwman (PBL Netherlands Environmental Assessment Agency), Chenmin He (Peking University), Barry B. Hughes (Frederick S. Pardee Center for International Futures), Fintan Hurley (Institute of Occupational Medicine), Terry Keating (United States Environmental Protection Agency), Jonathan D. Moyer (Frederick S. # Executive summary

**Model-based scenario analysis can help in identifying ways to achieve the environmental targets of the Sustainable Development Goals (SDGs) and related multilateral environmental agreements (MEAs)** (*well established*).

Target-seeking scenarios provide insight into the required level of effort, promising measures, and possible synergies and trade-offs between these measures and a range of targets. The usefulness of scenarios can be illustrated by the successful use of such scenarios in the literature on climate policy. Scenarios can be used to explore different pathways for achieving long-term targets and provide insights into the costs and benefits of these pathways. There are important interrelations (synergies and trade-offs) between the achievement of the various SDGs and related MEAs. This means that strategies that aim to achieve sets of targets will have to take account for these interrelations. At the moment, scenarios that explore the fulfilment of a large set of SDG targets simultaneously are mostly lacking. An assessment of possible pathways must therefore rely on more narrowly focused scenarios in the literature. This does lead to a higher level of uncertainty and some clear knowledge gaps. {22.2}

**Overall, available scenario literature suggests that different pathways exist for achieving the targets, but that these pathways require transformative changes** (*established, but incomplete*). The rate of change in the pathways, required to meet the targets identified in Chapter 20, indicate that incremental environmental policies will not suffice. Significant improvements in resource efficiency with respect to land, water and energy are required. This includes large productivity gains in agriculture, significant improvements in nutrient-use and water-use efficiency, almost a doubling of the energy efficiency improvement rate and a more rapid introduction of 'carbon-free' energy options. Similarly, achieving full access to food, water and energy resources will require a clear break with current trends. {22.3; 22.4.1}

**Achieving the sustainability goals will require a broad portfolio of measures based on technological improvements, lifestyle changes and localized solutions** (*established, but incomplete*). The pathways emphasize a number of key transitions that are associated with achieving sustainable consumption and production patterns for energy, food and water, in order to provide universal access to these resources, while preventing climate change, air pollution, land degradation, loss of biodiversity, water scarcity, over-exploitation and pollution of the oceans. These transitions include changes in lifestyle, consumption preferences and consumer behaviour on the one hand, and cleaner production processes, resource efficiency and decoupling, and corporate responsibility on the other. {22.3}

**Concurrently eliminating hunger, preventing biodiversity loss and halting land degradation is possible by combining measures related to consumption, production and access to food with nature conservation policies** (*well established*). Several measures have been identified that together can help

minimize the associated trade-offs, including sustainable agricultural intensification (e.g. increased water- and nutrient-use efficiencies), shifts to low-meat diets, reductions in food loss and waste, improved access to food and nutrition management, landscape management and an expansion of protected areas. {22.3.1}

**The strong links between biodiversity loss and land use mean that more coordinated international action is needed** (*established, but incomplete*). Scenario literature clearly shows that meeting targets to halt biodiversity loss would not be feasible if land use follows projected business-as-usual trajectories. Also, other policies outside the realm of traditional nature conservation policies are urgently needed to protect biodiversity, such as those related to infrastructure development and climate change. Ensuring more coordinated policy action is therefore important at all levels – within national governments, but also internationally – in particular between land-use planning and biodiversity protection. {22.3.1}

**There are multiple pathways to reduce greenhouse gas emissions to levels consistent with the Paris Climate Agreement. Each, however, requires transformative changes and needs to be implemented rapidly** (*well established*). Measures that reduce greenhouse gas emissions include lifestyle changes (e.g. a shift to low-meat diets and a move to more public modes of transport), a doubling of energy efficiency improvement, a more rapid introduction of low- and zero-carbon technologies (including hydropower, solar and wind, and carbon-capture-and-storage), reduction of non-CO<sub>2</sub> greenhouse gas emissions and the use of land-based mitigation options (e.g. reforestation and bioenergy). Emission reduction measures need to be implemented rapidly, because the carbon budgets for achieving the Paris Agreement are very tight. As a broad guideline, the rate of decoupling CO<sub>2</sub> emissions from gross domestic product (GDP) needs to increase from the historic rate of 1 to 2 per cent per year to between 4 and 6 per cent per year between now and 2050 if the Paris Agreement targets are to be met. {22.3.2}

**Air pollution emissions can be reduced significantly, but pathways towards meeting the most stringent air quality guidelines are currently not available** (*established, but incomplete*). Introducing air pollution policies alone is often not enough to achieve stringent air quality standards. However, climate change mitigation (e.g. phasing out fossil fuels) also significantly reduces air pollutant emissions. As a result, scenarios that combine climate policies with stringent air pollution policies show strong reductions in emissions of particulate matter with diameter less than 2.5 µm (PM<sub>2.5</sub>), leading to a significant improvement in air quality in all regions. In the best case scenarios, less than 5 per cent of the population is projected to be exposed to PM<sub>2.5</sub> levels above the World Health Organization's most lenient interim target of 35 µg/m<sup>3</sup>, though more than half of the population is still projected to be exposed to levels above the guideline of 10 µg/m<sup>3</sup>. {22.3.2}

**Reducing global water stress, including groundwater depletion, requires more efficient water use, increasing water storage and investing in wastewater reuse and desalination capacity** (*established, but incomplete*). To maintain or even reduce the global population suffering from water scarcity by 2050 and beyond, water-use efficiency needs to improve by more than 20-50 per cent globally. This includes increasing agricultural water productivity, improving irrigation efficiency and more efficient water use in domestic and industrial sectors. Wastewater reuse and desalination strategies require a large amount of economic investment and modernizing of existing infrastructure, which might not be feasible for many developing countries. Alternatively, nature-based solutions can increase and / or regulate water supply by mitigating water pollution, while limiting economic investments. {22.3.3}

**Achieving environmental targets related to oceans requires consistent policies in other sectors** (*well established*).

Preventing ocean acidification is highly dependent on climate change mitigation (i.e. reduced CO<sub>2</sub> emissions). Reducing marine nutrient pollution, and related hypoxia and harmful algal blooms, requires a significant reduction in nutrient run-off, primarily from fertilizer use and untreated wastewater {22.3.4}

**Ending preventable death of children under five years of age requires continued efforts to reduce environmental risk factors, but also increased emphasis on poverty eradication, education of women and girls, and child and maternal health care** (*established, but incomplete*). Ending hunger and achieving universal and equitable access to safe drinking water, adequate sanitation and modern energy services would improve health significantly – especially for children under five. However, even if all the environment-related SDG targets were achieved by 2030, the under-five mortality target would not be met. A healthy planet alone is not enough for healthy people. Achieving the SDG target on child mortality also requires addressing non-environmental risk factors, including poverty alleviation, education of women and girls as well as child and maternal health-care. {22.3.5}

**Understanding interlinkages between measures and targets is crucial for synergistic implementation and policy coherence** (*well established*). Where measures generally aim at achieving specific targets, or clusters of targets, they can also affect other targets. Integrated approaches are needed to grasp the synergies and deal with the potential trade-offs to achieve the environmental targets simultaneously. {22.3; 22.4.2}

**Overall, the literature reveals more synergies than trade-offs within and among the SDGs and their targets** (*established, but incomplete*). Significant synergies across human well-being and natural resource targets can be harnessed. For example, reducing agricultural demand by changing dietary patterns towards less meat intake and reducing food loss and waste, reduces the pressure on land and water, thereby reducing biodiversity loss and contributing to climate change mitigation. Other examples discussed in the chapter include education and reducing air pollution. Phasing out unabated use of fossil fuels leads to important co-benefits by achieving both climate and air quality targets, the latter having synergies with improving human health, increasing agricultural production and reducing biodiversity loss. {22.4.2}. The chapter also identifies several trade-offs. This could imply that such measures are less attractive or additional policies are needed to mitigate the trade-offs. {22.3}

**Yield improvement and bioenergy are important measures to address biodiversity loss and climate change, respectively, but they can conflict with achieving other targets** (*well established*). While nearly all scenarios consistent with the Paris agreement rely on land-based mitigation measures, their use increases demand for land, with related biodiversity impacts, and they potentially lead to higher food prices. Increasing agricultural yields can improve overall food availability and reduce pressure on natural land but could also, through higher levels of water, pesticide and fertiliser use and mechanization, lead to land degradation, water scarcity, hypoxia and harmful algal blooms and biodiversity loss. {22.4.2}

**Further model development and pathway analysis is needed to cover a wider set of linkages across the SDGs** (*well established*). The scenario literature is still patchy with respect to achieving a broad range of targets. Climate change and land-use issues are well covered, while scenarios addressing land degradation and many challenges related to oceans, but also to chemicals and waste, are mostly lacking. Furthermore, many synergies and trade-offs are discussed in the literature, but besides thematic studies, a thorough overview of all relevant interrelations is lacking. More dedicated analyses are required, including systematic reviews of the existing literature and dedicated integrated assessment modelling, with specific attention to interlinkages that are currently underexplored. {22.5.1}

## 22.1 Introduction

The identified targets associated with the environmental dimension of the Sustainable Development Goals (SDGs) and related Multilateral Environmental Agreements (MEAs) from Chapter 20 will not be achieved under current trends (Chapter 21). This chapter assesses the scenario literature for possible pathways that would achieve those targets, thereby closing the implementation gap (**Table 21.2**). The focus is on the question of what would be needed to achieve these targets – and what are important synergies and trade-offs between different measures and these targets. This chapter does not discuss the social or political feasibility of the pathways. Moreover, the focus is on measures (e.g. energy efficiency improvement or changes in yield) and not on the policies to implement these measures (e.g. taxes or regulation). The latter will be discussed further in Chapter 24.

A range of scenarios can be found in the literature that analyse how to implement specific targets such as those related to climate change or land-use change (e.g. Global Energy Assessment [GEA] 2012; Clarke *et al.* 2014; Obersteiner *et al.* 2016). Scenarios that address achieving multiple environmental and/or development targets at the same time are far more scarce, with only a few exceptions (e.g. van Vuuren *et al.* 2015; The World in 2050 Initiative [TWI2050] 2018). Furthermore, there is no comprehensive study that explores all the key interrelations between a broad set of measures and SDG targets. Such studies are important, as the SDG targets and those related to MEAs depend on each other in different ways, leading to both synergies and trade-offs in response strategies (Nilsson, Griggs and Visbeck 2016). This gap in the literature means that, in our assessment, the required measures and the interrelations between different targets need to be based on interpretation of existing work.

## 22.2 Pathways definition

A range of different scenarios exist that describe a move towards sustainable development (see van Vuuren *et al.* 2012 for an overview of different scenario types). Some scenarios explore the consequences of introducing a set of assumptions about key drivers (e.g. population, economic development and technology) consistent with an emphasis on sustainable development. These subsequently look at the impacts for human development and the environment. Examples include the SSP1 (Sustainable Development) scenario of the Shared Socio-economic Pathways (SSPs) (Riahi *et al.* 2017; van Vuuren *et al.* 2017a; **Box 21.2**), the TechnoGarden scenario of the Millennium Ecosystem Assessment (Millennium Ecosystem Assessment 2005) and the Great Transition Scenarios of the Global Scenarios Group (Raskin *et al.* 2002). These scenarios all lead to relatively positive developments for environmental problems, although they typically do not reach all the targets introduced in Chapter 20. Other scenarios apply a 'back-casting approach' – showing pathways towards reaching a set of sustainable development objectives (e.g. the Road from Rio+20 scenarios; see **Box 22.1**). Two recent scenarios focus specifically on the role of lifestyle change and the possible implications for climate change mitigation (Grubler *et al.* 2018; van Vuuren *et al.* 2018). Sustainable development scenarios differ from current trend scenarios (see Chapter 21) in many ways – including in the nature of economic activities and personal lifestyles, the availability and performance of

technologies, and the interventions, regulations and policies that are applied – leading to differences in associated levels of effort, and synergies and trade-offs that will be required to achieve sustainable development (PBL Netherlands Environmental Assessment Agency 2012).

This chapter assesses available scenarios in the literature. No new scenarios were developed. The scenarios cited here should be seen as illustrations of possible pathways towards sustainable development and not as well-defined blueprints. Where possible, SSP-derived scenarios are used (**see Box 21.2**). Furthermore, the storylines of the Roads from Rio+20 study are used to show that there are different ways to strengthen and direct, or redirect, technologies, preferences and incentives in society towards sustainable development (van Vuuren *et al.* 2015; **Box 22.1**). As such, the underlying dimensions of the Roads from Rio+20 study can also be used to qualify the measures analysed in this chapter. The first dimension then makes the distinction between options that depend on global cooperation and those that specifically focus on the local situation (mostly related to ensuring heterogeneity and local governance). The second dimension distinguishes between options that focus on introducing more sustainable production patterns versus more sustainable consumption patterns. The Roads from Rio+20 scenarios can also be mapped on these dimensions (**Figure 22.1**). It should be noted that, so far in model-based scenario analysis, strategies based on making production patterns more sustainable have received more attention than strategies focused on changing consumption patterns.

**Figure 22.1: The scenarios from the Roads from Rio+20 study**

These scenarios are based on a different focus along the dimensions global versus local interventions and production- versus consumption-side orientation. The scenarios are used in this chapter to illustrate that there are different strategies in moving towards sustainable development.

## 22.3 Pathways towards achieving the targets

A range of measures identified as necessary to achieve the selected targets (see Chapter 20) are listed in **Figure 22.2**. These measures are linked to the five clusters of closely related

## Box 22.1: Roads from Rio+20

The Rio+20 study looked into model-based pathways that simultaneously achieve a broad set of long-term environment and development targets (van Vuuren *et al.* 2015). The pathways were developed using the IMAGE integrated assessment model. The targets were based on existing, pre-2012, international agreements (SDGs *avant-la-lettre*). The study focused on two key sets of related challenges:

1. Eradicating hunger and halting biodiversity loss;
2. Universal access to modern energy and mitigating climate change.

The study further addressed trade-offs with water, nutrients and health. The study introduced three possible pathways towards achieving sustainability targets: (1) global technology, (2) decentralized solutions, and (3) lifestyle change. The different trajectories for the alternative scenarios can be explained by the differences in perceived urgency, economic and institutional effectiveness, and feasible rate of lifestyle changes. The scenarios can be characterized as follows:

- ❖ **Global technology:** In the global technology pathway, international and national decision makers feel an urgency to deal with global sustainability issues and manage to convince most citizens to introduce large-scale, global solutions to resolve these issues. The problems and solutions are primarily perceived and solved as large in scale and global in outreach.
- ❖ **Decentralized solutions:** The belief that a sustainable quality of life can only be realized at the local or regional level gets more priority than the possible impacts of long-term issues. As a result, sustainability problems are primarily seen and resolved in the form of small-scale and decentralized technologies and organizational efforts. Local 'smart' solutions may also fall into this strategy. This is a 'bottom-up' evolving world.
- ❖ **Consumption change:** Partly because there is a growing awareness of sustainability issues, important changes in lifestyle take place that facilitate a transition towards less material- and energy-intensive activities. Targets that still have not been achieved are bridged with additional existing technologies.

Figure 22.2: Selected measures and their related clusters as examined in this chapter

|                                        | Agriculture, food, land and biodiversity                                                                                                                                                                                 | Energy, air and climate                                                                                                                                                                                                                                                                          | Fresh water                                                                                                                                                                          | Oceans                                                                                                                                           | Human health                                                                                                                          |

environmental issues and the three groups of SDGs, mirroring the framework of **Figure 22.1**. Note that, in line with Chapter 21, targets associated with production and consumption, such as the rate of yield improvement or energy intensity improvement, are discussed as means to achieve the desired situation. They are discussed within the different clusters and summarized in the synthesis at the end of this chapter.

The following sections review the scenario literature for pathways to achieve the targets within each cluster, discussing the measures required for achieving the targets, and potential synergies and trade-offs between the different measures and targets within each cluster.

In Part A, chemicals and waste, and wastewater were also identified as a major global environmental problem. As explained in **Box 21.1**, there is not a lot of specific scenario literature on these issues. We do discuss reducing food loss and waste in the agriculture, food, land and biodiversity cluster. In the energy, air and climate and freshwater clusters, we pay attention to increasing efficiency – which addresses the issue of wasting energy and water, as well as wastewater treatment.

### 22.3.1 Agriculture, food, land and biodiversity

The selected targets for the agriculture, food, land and biodiversity cluster can be summarized as ending global hunger, while at the same time halting biodiversity loss and achieving land-degradation neutrality (see Chapter 20). Selected targets that contribute to achieving these endpoint targets include increasing agricultural productivity and increasing nutrient-use efficiency.

Without additional measures, none of these three targets are projected to be met (Chapter 21). While hundreds of millions of people are projected to still be undernourished in 2050, agricultural area is projected to expand by between 150 and 425 million ha between 2010 and 2050, resulting in declines in natural area, including forests. Biodiversity projections suggest a further decline in species richness and abundance, and land degradation is projected to continue. Achieving the targets requires a major transformation of the food production system, the main driver for human-induced land-use change.

With respect to ending hunger, the Food and Agriculture Organization of the United Nations (FAO) definition of food security is used: “Food security exists when all people, at all times, have physical and economic access to sufficient, safe and nutritious food that meets their dietary needs and food preferences for an active and healthy life” (FAO 1996). In practice, not all scenarios include enough information to assess all aspects of this definition. Therefore, we have taken qualitative descriptions of the scenarios to assess whether the target is met. For biodiversity, the target is based on the Convention on Biological Diversity (CBD) strategic plan for biodiversity 2011-2020 (CBD 2010), translated to halt biodiversity loss by 2020 for developed countries and from 2030 onward for developing countries (Kok *et al.* 2018). Halting biodiversity loss is therefore taken to mean preventing further declines in the diversity within species, across species and within ecosystems, as well as the abundance and coverage of these organisms. For achieving land degradation neutrality no quantitative analysis is available.

There are important linkages between this cluster and other cluster targets. For instance, combating climate change might require significant amounts of bioenergy and land devoted to its production. Total land area dedicated to bioenergy production is a major uncertainty in future scenarios, especially those with stringent emissions abatement targets (Popp *et al.* 2014). In addition, increased agricultural production could require increasing inputs of freshwater, nitrogen and phosphorus.

In order to simultaneously end hunger and prevent biodiversity loss and further land degradation, enough food needs to be produced to feed a global population of 9-10 billion people by 2050 without expanding agricultural land (at least on a global scale). At the same, there will also be other demands for land such as biomass production for energy and demand to produce timber. Reducing hunger not only requires sufficient production, but also, much more importantly, issues of access (economic and physical) will need to be addressed in order to ensure that all people receive adequate food. Additionally, this needs to occur with minimal pollution (nitrogen, phosphorus or other). Further land protection and land restoration may be required to prevent biodiversity loss and avoid or reverse land degradation.

There are several scenarios in the literature that achieve these targets in an integrated way. These studies show that there are multiple routes for achieving the targets, such as via more technology-focused routes, changing demand or focusing more on governance structures, land tenure and creating markets (Tilman *et al.* 2011; Bajželj *et al.* 2014; van Vuuren *et al.* 2015; Obersteiner *et al.* 2016). More recent literature based on the SSPs discusses multiple routes that could lead to zero hunger by 2050 (Hasegawa *et al.* 2015), some of which are achieved without expanding agricultural area (Popp *et al.* 2017). However, it is important to note that food security involves not just security of supply but also demand factors such as access to food, including affordability and distributional concerns (Qureshi, Dixon and Wood 2015), and its nutritional value. However, issues of access, distribution and nutritional value are largely excluded from the scenario literature and thus not discussed in depth in this chapter.

Most scenario studies that discuss prevention of biodiversity loss assume a suite of land-, agriculture- and biodiversity-related measures acting together, including increasing agricultural productivity, reducing consumption of meat, dairy and eggs, reducing food loss and waste, avoiding fragmentation and expanding protected areas. Such measures can reduce biodiversity loss (van Vuuren *et al.* 2015) and extinction risks for birds and mammals (Tilman *et al.* 2017).

Overall, a broad range of measures is discussed in the literature, including measures related to agricultural production, agricultural demand-side measures and measures that aim for protection of terrestrial ecosystems.

#### **Measures related to agricultural production**

One option to achieve the targets in the agriculture, food, land and biodiversity cluster is to change agricultural production patterns. This includes yield improvement (to avoid further expansion of agricultural land), but also other efficiency measures, such as for nutrient and water use, to reduce the environmental pressure of agriculture.

### Improving yield

In the SSP2 baseline (Fricko *et al.* 2017), between 2010 and 2050, per capita demand for food, feed and energy crops increases by 60 per cent. In the same period, global average aggregate food, feed and energy crop yields (mean tons of agricultural products per hectare) also increases (by around 1.0 per cent per year). As a result, the net effect in SSP2 is an increase in cropland area of about 15 per cent in 2050 (230 million ha) (**Figure 22.3**). This is in line with the FAO projection for yield improvements and agricultural area expansion through 2050 (Alexandratos and Bruinsma 2012). To limit cropland expansion, yield growth would need to increase from around 1.0 to 1.4 per cent per year. It is thus useful to look into the evidence on the question whether fast yield improvements are possible in the future. First, similar yield improvement rates have been achieved historically (Alexandratos and Bruinsma 2012). Moreover, several scenarios indeed show high future yield increase (**Figure 22.3**). There is also a large yield gap between the most- and least-productive regions (Global Yield Gap and Water Productivity Atlas 2018),

**Figure 22.3: Percentage change in non-energy crop production versus the percentage change in non-energy cropland area from 2010 to 2030 and 2050**

Each marker is a model-scenario-year combination. Colour indicates the annual percentage change in yield over the same time period. Yellow is close to historical trends (about 1 per cent per year between 1960 and today from Alexandratos and Bruinsma 2012); blue indicates yield growth faster than historical trends; red indicates yield growth slower than historical trends. For the SSPs, yield is the global average yield for cereal crops. For the Bajželj *et al.* (2014) scenarios, yield is the global average yield for wheat and data are referenced with respect to 2009.

Sources: SSPs (Popp *et al.* 2017) and Bajželj *et al.* (2014).

and transfer of best practices from the leaders to the laggards might raise global average yields (Neumann *et al.* 2010; Foley *et al.* 2011). Finally, new methods to improve yields might also provide further potential (including genetically modified organisms [GMOs]). On the other hand, the easy yield gains may already have been achieved (Slade, Bauen and Gross 2014). Moreover, over the past decades yield increases have coincided with significant increases in environmental pressure such as nitrogen pollution as a result of nitrogen fertilization (Lassaletta *et al.* 2016). Projections of future fertilizer use are uncertain, but it is clear that increasing global production levels would require greater fertilizer use (Alexandratos and Bruinsma 2012). For instance, yield increase could lead to 15–70 per cent increase in nitrogen losses to the environment, leading to further pollution of water and soil (Sutton and Bleeker 2013; Lassaletta *et al.* 2016). Sustained yield improvements may also be reliant on increased irrigation, impacting water resources (Neumann *et al.* 2010). It is also possible that in the future organic farming coupled with reduced food waste and diet change could considerably reduce the environmental footprint of agriculture (Muller *et al.* 2017). However, one might question whether such measures would lead to similar yield levels as through conventional agriculture (Leifeld 2016), or the scalability of existing experiences in both alternative production and food waste reduction methods (Schneider *et al.* 2014). For pasture area, the intensification of livestock production could limit the increase in pasture area, and possibly lead to a decrease.

### Reducing environmental pressures associated with agriculture

High-yield agricultural systems are usually associated with high levels of nitrogen loss as reported in the previous section. There is evidence, however, that the negative impact of high-yield agriculture on nitrogen loss could be limited by improving nitrogen-use efficiency (Lassaletta *et al.* 2016; Bouwman *et al.* 2017). This can be shown by the large variation in application rates, with excess application in some regions leading to significant environmental impact, especially in China (Zhang *et al.* 2016; Cui *et al.* 2018). In fact, rapidly increasing global nitrogen-use efficiency from the current 40 per cent to close to 70 per cent may lead to a sharp decline in excess nitrogen to 50 Tg N/year, with the added benefit of potentially leading to stabilization of total nitrogen inputs in global crop production (Zhang *et al.* 2015). Mogollon *et al.* (2018) present similar findings but emphasize that this can only happen in optimistic sustainability scenarios (limited increase in demand and high efficiencies). The relationship of crop yield to nitrogen application means there are diminishing returns to higher nitrogen application in regions with high fertilizer application rates and more potential for increased production in regions with low application rates. This means there is room globally to optimize nitrogen application. The trade-off in this case would be an increase in international trade of agricultural commodities.

It is also important to reduce other environmental pressures – such as high levels of water consumption (see Section 22.3.3), the negative impacts of use of herbicides and pesticides, and eutrophication of inland and coastal waters due to excess nutrient use in food production and sewage water discharge. Scientific evidence shows that it is important to maintain agricultural sustainability to ensure services such as natural pest control, pollination and fertility (Oerke 2006; de Vries *et al.* 2013; Garibaldi *et al.* 2017). For instance, except for cereals (which are not insect-pollinated), many important global food

crops depend, at least partly, on animal pollinators (usually insects) for yield and/or quality, and pollinator-dependent crops contribute 35 per cent of the global crop production volume (Klein *et al.* 2007). Reducing negative impacts can to some degree be achieved in high-yield agricultural systems. There is some evidence that organic farming could be an alternative as it may support greater local species richness and higher densities of natural organisms compared with conventional farms (Bengtsson, Ahnström and Weibull 2005; Tuck *et al.* 2014). However, organic farming could also lead to lower yields and thus increased land use (Clark and Tilman 2017). The role of organic farming cannot be really assessed in this chapter as, at present, the issue of organic farming is hardly addressed in scenario studies. In fact, the same goes for strategies to preserve sufficient genetic diversity. While there is some evidence that it is important to maintain diversity as a buffer against all kinds of environmental variability, again this is not really addressed in scenario studies. Such diversity can be encouraged by rotating crops, intercropping and varying crop varieties.

#### *Preventing land degradation*

The loss of soil organic carbon and other forms of soil degradation can significantly impact crop yields and the nutritional values of food produced (Godfray *et al.* 2010; Lal 2015; Rojas *et al.* 2016). Therefore, maintaining soil health, through the management of soil organic carbon and preventing land degradation, is important. The recently published Global Land Outlook is one of the few studies that discuss land degradation in the context of different scenarios, but it only discusses trend scenarios and not pathways towards achieving the land degradation neutrality target (United Nations Convention to Combat Desertification [UNCCD] 2017; van der Esch *et al.* 2017). Land restoration and protection targets are projected to increase tree cover by 4 million km<sup>2</sup> in 2050 compared to the area in 2000 and increase forest carbon stocks by 50Gt over the same time period (Wolff *et al.* 2018). However, due to the limited scenarios literature, it is hard to assess the role of avoiding land degradation in achieving the SDGs.

#### **Agricultural demand-side measures**

To limit cropland expansion, it is also possible to reduce the food demand that would occur in baseline projections. Reductions in demand could come from reduced food consumption, reduced waste or reduced feed/fuel uses of crops.

#### *Dietary change*

Changes in diet are considered an effective measure for reducing land-use impacts of agriculture. Diet changes resulting in less meat consumption would reduce crop use as animal feed, which in turn would reduce demand for land, since direct human consumption of crops requires less land (Stehfest *et al.* 2009). In particular, a reduction in beef consumption would have the most direct positive impact on environmental indicators, as ruminants have the lowest feed and protein conversion rates of all livestock (Béné *et al.* 2015). This implies that reduction of meat consumption to levels consistent with health recommendations in high-income countries could lead to positive impacts in terms of reducing agricultural land-use and increasing human health (Stehfest *et*

*al.* 2009) – as on average current consumption of beef is above this level. Strong reductions in land area for food production as a result of dietary shifts towards more plant-based diets have been reported by Foley *et al.* (2011) and Stehfest *et al.* (2009). Such a shift would also lead to health benefits, according to these studies. Land-efficiency gains can also be gained by eating different meat. Meat from non-ruminant livestock (e.g. pigs) has a lower impact than beef, and the land footprint of their diets can be improved by shifting to more efficient (higher-yielding) fodder crops (Béné *et al.* 2015; van Zanten *et al.* 2018). Thus, diets based on lower shares of ruminants would reduce land demand. In the case of bivalves, aquaculture may even remove nutrient run-off into estuaries through filtration, a potential synergy.

More recent scenarios in the literature have also focused on dietary change, including the SSP1 scenarios (see Popp *et al.* 2017), and the ‘consumption change’ pathway from Roads from Rio+20 (van Vuuren *et al.* 2015; van Vuuren *et al.* 2018) and others (Bajželj *et al.* 2014; Tilman and Clark 2014). The dietary change ranges from modest shifts towards non-ruminants (the SSP1 scenario) to complete elimination of meat (Tilman and Clark’s Vegetarian scenario). Several of these scenarios limit the expansion of cropland area, but these also include enhanced yields, suggesting that dietary change alone is not enough to limit cropland expansion given a growing population. Note that, in addition to changes in yield and diet, these scenarios also have limited expansion of bioenergy cropland (60 and 140 million ha in 2050 in the SSP1 scenario of the IMAGE and GCAM models, respectively). In the end, this means that a combination of yield improvement, diet change and control of bioenergy expansion offers the most likely situation in which expansion of agricultural area can be avoided.

#### *Waste and loss reduction*

Global agricultural production in 2010 (about 3,900 kcal of food crops per person per day) was more than enough food to feed the world, yet more than 800 million people were undernourished (Alexandratos and Bruinsma 2012; Kummu *et al.* 2012). One reason is that 25-40 per cent of food produced is wasted, either through supply-chain waste or end-consumption waste (Godfray *et al.* 2010; Kummu *et al.* 2012). Reducing food waste and loss is one way of reducing hunger, while limiting cropland expansion. The amount of food wasted today is enough to feed several hundred million people a year (West *et al.* 2014), with some studies showing that if half of this waste were redistributed to consumers an extra billion people could be fed (Kummu *et al.* 2012). Similarly, Bajželj *et al.* (2014) show that cutting food waste in half would reduce cropland area by 14 per cent. Muller *et al.* (2017) show that, in addition to reducing land demand, dietary change and waste reduction can result in reduced fertilizer and water use. Bijl *et al.* (2017) show that, although significant improvement can be achieved through yield increase, the improvement is less than expected – mostly because meat is, on average, wasted less than other agricultural products. Several of the scenarios that look into waste reduction also report limited cropland expansion (consumption change from van Vuuren *et al.* 2015 and some scenarios of Bajželj *et al.* 2014). Each of these scenarios also assumes enhanced yields leading to the conclusion that waste reduction alone is not enough to limit cropland expansion given an increasing population.

### Changes in food distribution

Hunger is to some degree a function of available calories, but more importantly the distribution of these calories. Income distribution plays a key role in food distribution (Wanner *et al.* 2014; Hasegawa *et al.* 2015). In their analysis, Hasegawa *et al.* (2015) conclude that future developments in global hunger are mostly determined by population growth, inequality in food distribution and per capita domestic food production. Improving access to food for the poorest households significantly reduces the required increase in food production to feed the global population in 2050 (van Vuuren *et al.* 2015). Also avoiding food waste reduces demand for cropland and could still allow for meat consumption, albeit at a lower rate than current-trend projections (Röös *et al.* 2017).

In baseline scenarios, childhood stunting and wasting are also projected to decrease, but not enough to achieve the SDG target of elimination by 2030 (Global Burden of Disease [GBD] 2015 SDG Collaborators 2016; GBD 2016 SDG Collaborators (2017). Meanwhile, the prevalence of overweight children has been increasing over the past 15 years (GBD 2015 SDG Collaborators 2016): fewer than 5 per cent of countries are projected to achieve the SDG target for overweight children (GBD 2016 SDG Collaborators 2017). Achieving these targets therefore requires accelerated action on nutrition as well as the more distal drivers of poor health outcomes – poverty, low levels of education and health spending, as well as conflict (GBD 2016 SDG Collaborators 2017; see also Section 22.3.5).

### Maintaining terrestrial biodiversity

The baseline scenarios covered in Chapter 21 show a further decline in biodiversity. Some scenarios have been published that specifically look into how to halt biodiversity loss (e.g. van Vuuren *et al.* 2015; Obersteiner *et al.* 2016; Kok *et al.* 2018; Leclerc *et al.* 2018). These scenarios show that, in addition to preserving terrestrial biodiversity in protected areas, it will be at least as important to reduce the external drivers that lead to loss of biodiversity such as expansion of land use, climate change and expansion of infrastructure. We briefly discuss some of these elements below. All-in-all, the scenario literature suggests that pathways to halting biodiversity loss exist – but that such scenarios will be difficult to implement.

### Protecting terrestrial ecosystems

Protected areas are a key land management conservation tool. Syntheses have demonstrated that, compared with other locations, the diversity of species within protected areas tends to be 10 per cent greater and the abundance of species 15 per cent greater (Coetzee, Gaston and Chown 2014; Gray *et al.* 2016). Also, habitat conversion rates are 7 per cent lower within protected areas (Geldmann *et al.* 2013). While the CBD's Aichi Target 11 suggests a 17 per cent coverage target, in 2016 protected areas occupied 14.6 per cent of the terrestrial land area. As shown in Chapter 21, current trends will lead to a dramatic loss of biodiversity. Therefore, coordinated international action is urgently needed to balance land-use decision-making and biodiversity conservation. Expansion of the protected land area by 5 per cent in a well-designed way could lead to a significant increase in the protection of biodiversity (Pollock, Thuiller and Jetz 2017). Many scenarios in the literature have explicit assumptions on protected area trends. However, protected area expansion should not be the only consideration and should not come at the expense of effective management of current protected areas (Barnes *et al.*

2018). Furthermore, environmental policy outside of the formal protected areas network is of critical importance.

### Land ownership

Land ownership has implications for land management and can therefore have implications for biodiversity residing on it. For example, private versus publicly owned lands have different bird species compositions (Maslo, Lockwood and Leu 2015) and private temperate forests contain a greater diversity and density of microhabitats that can support greater biodiversity (Johann and Schaich 2016). Over one-quarter of the whole terrestrial land surface is managed or under the tenure rights of indigenous groups and this land intersects with approximately 40 per cent of protected areas and ecologically intact landscapes (Garnett *et al.* 2018). In addition to public and private land ownership, local committees, and indigenous peoples' land rights and the manner in which they manage that land is therefore likely to be essential to meeting local and global conservation goals. Assessing the role of land ownership in pathways towards sustainability beyond this is difficult, however, because land ownership is seldom incorporated explicitly into scenario exercises.

### Land-use planning

Land-use planning involves the systematic assessment of environmental, economic and social impacts of the range of potential uses of land in order to decide on the optimal pattern of land use. Land-use planning and systematic conservation planning has seldom been explored explicitly as a tool in global scenarios. The most noteworthy exceptions are the recent scenarios by Leclerc *et al.* (2018) that use the biodiversity value of land areas to determine optimal land use and also can inform GEO assessments in the future. They find that such an approach in land-use planning can indeed contribute to a strategy that aims to halve biodiversity loss.

### Forest management

Meta-analysis shows that different categories of forest management types have different implications for biodiversity loss, with selection and retention systems having the least detrimental effect on species diversity, while timber and fuelwood plantations have the worst effect (Chaudhary *et al.* 2016). Although forest management practices are not always explicitly represented in scenario simulations, studies suggest that consistent implementation of any single management regime results in suboptimal biodiversity outcomes compared with an optimal combination of management regimes (Monkkonen *et al.* 2014).

### Significant trade-offs across the targets

A number of trade-offs can be identified between specific measures and the various targets within this cluster. Three important ones are as follows.

- ❖ Increases in cropland area can help reduce hunger by enabling increased food production. This expansion is included in many of the scenarios in the literature (e.g. Tilman *et al.* 2011; Bajželj *et al.* 2014; Tilman and Clark 2014; Popp *et al.* 2017). However, expansion of cropland area can lead to clearing of natural lands and increased land-use change emissions, which have implications for biodiversity, land degradation and climate change. Note that limiting the expansion of cropland area has implications for crop yields, fertilizer use and energy crop

production as well (see Chapter 5 and Sections 22.3.2). Additionally, limiting cropland expansion could have implications for development (Sandker, Ruiz-Perez and Campbell 2012).

- ❖ Increasing fertilizer application rates may help increase agricultural yields in regions with persistent yield gaps but can also have severe consequences for freshwater and coastal ocean eutrophication, and climate change, with excess nitrogen and phosphorus run-off potentially impacting water quality (Beusen *et al.* 2016; Bouwman *et al.* 2017). On the other hand, sustainable intensification of agriculture (e.g. through precision agriculture) can help deliver higher yields while preserving ecosystem services and reducing environmental impacts (Foley *et al.* 2011; Garnett *et al.* 2013; Garbach *et al.* 2017). Increasing global nitrogen-use efficiency can reduce nitrogen run-off to the environment (see Chapter 8).
- ❖ Monoculture plantations of exotic, fast-growing trees have been used to maximize carbon sequestration (Chazdon 2008; Hunt 2008), negatively impacting local biodiversity. However, plantations of multiple native species can be an effective alternative (Hulvey *et al.* 2013; Cunningham *et al.* 2015), while also providing greater benefits for biodiversity (Bradshaw *et al.* 2013). Furthermore, natural regrowth is an alternative to plantations that has been shown in tropical forests to be more ecologically beneficial, cost-effective and resilient (Crouzeilles *et al.* 2017).

### 22.3.3.2 Energy, climate and air

The selected targets for the energy climate and air cluster can be summarized as the challenge to achieve universal access to modern energy services, while at the same time combating climate change and improving air quality (see Chapter 20). Selected targets that contribute to achieving these endpoint targets include improving energy efficiency and increasing the share of renewable energy.

Under current trends, none of these three targets are projected to be met (Chapter 21). By 2030, more than 2 billion people are still projected to cook on traditional biomass stoves or open fires and around 700 million people do not have access to electricity. The global mean temperature is projected to increase further, while a significant share of the global population is still exposed to concentrations of particulate matter with diameter less than 2.5  $\mu\text{m}$  ( $\text{PM}_{2.5}$ ) above 35  $\mu\text{g}/\text{m}^3$ . Achieving these targets requires a major transformation of the energy system.

Modern energy services include electricity and clean fuels for cooking, heating and lighting, with 'clean' defined by the emission rate targets and specific fuel recommendations (i.e. compared to unprocessed coal and kerosene) of the World Health Organization (WHO) guidelines for indoor air quality (WHO 2014). Combating climate change means keeping the global mean temperature change well below 2°C and if possible below 1.5°C (United Nations Framework Convention on Climate Change [UNFCCC] 2015). Improving air quality means air pollution levels should, in the long term, be consistent with the WHO guidelines – that is, the interim target of annual mean  $\text{PM}_{2.5}$  concentration should be below 35  $\mu\text{g}/\text{m}^3$  by 2030 (WHO 2006).

There are important linkages between this cluster and other cluster targets. For instance, most low-carbon pathways that limit global mean temperature to 2°C (or 1.5°C) include significant amounts of bioenergy. The role of land-based ecosystems, both natural and managed, is essential for achieving net-zero and net-negative emissions.

There is a rich literature of scenarios that have looked at the challenge of meeting ambitious climate targets (for an overview, see Clarke *et al.* 2014, and more recent studies including Riahi *et al.* 2017; Rogelj *et al.* 2018; van Vuuren *et al.* 2018). Fewer published scenarios have looked at meeting ambitious energy access targets (e.g. Pachauri *et al.* 2013; International Energy Agency [IEA] 2017) or air pollution targets at a global scale (e.g. Rao *et al.* 2017). A broad range of measures is discussed in the literature, including improving energy access (electricity and clean cooking fuels), reducing greenhouse emissions by addressing both energy demand and production, and air pollution control.

#### Improving access to energy

Universal access to modern energy services will not be achieved by 2030 in a baseline scenario, particularly not in sub-Saharan Africa (for electricity and clean fuels and technologies) and in Asia (mainly clean fuels and technologies) (see Chapter 21). Achieving universal access to electricity requires further expansion of generation capacity and transmission and distribution networks, as well as access to more efficient and affordable appliances, with a specific focus on poor, remote communities (GEA 2012; IEA 2017; Lucas, Dagnachew and Hof 2017). To achieve universal access to clean fuels and technologies, the affordability, availability and safety of fuels and practices for cooking, heating and lighting should be improved (Modi *et al.* 2006). Improved fuels include liquified petroleum gas (LPG), natural gas and electricity in urban areas, and a range of technologies (including biogas and the use of advanced biomass cookstoves) in rural areas (IEA 2017). Modelling studies have shown that there are different pathways to achieve universal access to modern energy services (Pachauri *et al.* 2013; Dagnachew *et al.* 2017).

The choice of the electrification system – grid-based, mini-grid or off-grid – depends on a range of mostly local factors, including the level of household electricity demand, the distance to the existing grid and local resource availability (Dagnachew *et al.* 2017). Grid-based electrification is attractive for densely populated areas with an expected high demand for electricity and/or within a reasonable distance of existing high voltage power lines, while decentralized electrification systems are key to reaching out to semi-urban areas with low consumption density, and remote rural areas (Dagnachew *et al.* 2017; IEA 2017; Lucas, Dagnachew and Hof 2017). Total annual investments to achieve universal access are estimated at US\$52 billion globally (IEA 2017) and US\$24-49 billion in sub-Saharan Africa alone (Dagnachew *et al.* 2017; Lucas, Dagnachew and Hof 2017), depending primarily on total household electricity demand and the cost of high-voltage transmission and distribution.

Policies that could encourage a transition to clean fuels and technologies for cooking, heating and lighting include fuel subsidies and grants or microlending facilities to make access

to credit easier and lower households' cost of borrowing (Riahi *et al.* 2012). The use of improved or advanced biomass stoves may in fact lead to economic gains instead of costs, as the investments would be countered by the reduction in spending on fuelwood (van Ruijven 2008). Total required investments to achieve universal access to clean fuels for cooking, heating and lighting are projected to be less than 10 per cent of what is needed for achieving universal access to electricity (Pachauri *et al.* 2013; IEA 2017). Improving access to clean fuels can significantly improve health (Pachauri *et al.* 2013; Landrigan *et al.* 2018). Climate policy can induce energy savings, reducing the overall investment required for achieving universal access (Dagnachew *et al.* 2018).

### Reducing greenhouse gas emissions

The Paris climate targets set very stringent constraints for the development of future energy systems. Although some recent publications have shown that carbon budgets are subject to considerable uncertainty (Intergovernmental Panel on Climate Change [IPCC] 2018; Rogelj *et al.* 2016; Millar *et al.* 2017), the main message is that they are small compared to current emissions. To meet the Paris climate targets, cumulative CO<sub>2</sub> emissions from now onwards need to be in the order of 1000–1600 gigatons of CO<sub>2</sub> (2°) or even 300–900 gigatons of CO<sub>2</sub> (1.5°). The current emissions are in the order of 40–42 gigatons CO<sub>2</sub>/year (Le Quéré *et al.* 2016; IPCC 2018). Assuming a linear reduction without negative emissions, unabated fossil fuel use thus needs to be phased out somewhere around the middle of the century (van Vuuren *et al.* 2017a). This would require an immediate halt to investments into CO<sub>2</sub>-emitting technology, but possibly even a faster retirement of existing fossil fuel infrastructure (Johnson *et al.* 2015; Gambhir *et al.* 2017).

The option, however, also exists to actively remove CO<sub>2</sub> from the atmosphere, for instance by afforestation and bioenergy,

combined with carbon-capture-and-storage, direct-air-capture, enhanced weathering and increasing soil carbon (IPCC 2018). However, the amount of CO<sub>2</sub> that can be removed from the atmosphere in this way is not unlimited: both afforestation/ reforestation and bioenergy are restricted by the amount of land available, as well as possible impacts on biodiversity and food production (Smith *et al.* 2016). Moreover, the storage potential for CO<sub>2</sub> is limited (Koelbl *et al.* 2013). Among various options for CO<sub>2</sub> removal that have been assessed, under current technologies, only sequestration in geological formations is considered to have the capacity and permanence necessary to store CO<sub>2</sub> at the gigaton level, which is necessary to reduce CO<sub>2</sub> emissions significantly (Benson *et al.* 2012). While the estimated storage capacity is more than enough to meet emissions reduction targets, the estimates do not consider the risks associated with permanent storage (e.g. environmental contamination from leakage, seismic activities) (de Coninck and Benson 2014; Bui *et al.* 2018). Therefore, rapid emissions reduction will be needed in the short term regardless of the availability of negative emissions technologies (van Vuuren *et al.* 2017a). **Figure 22.4** shows the range of scenarios in the SSP database following the SSP2 baseline and those consistent with the Paris targets of well below 2°C (Riahi *et al.* 2017; Rogelj *et al.* 2018). The scenarios depicted here are based on low cost pathways, assuming an immediate response. There are several papers in the literature that show that a delayed response is more expensive and could even make it impossible to reach stringent targets (Riahi *et al.* 2015; Rogelj *et al.* 2018). Such delayed response would, for instance, occur if countries decide to follow the currently formulated climate policies and aim for a rapid implementation of climate policy after 2030.

Globally, energy-related CO<sub>2</sub> emissions would need to be reduced by around 60–70 per cent by the middle of the century in order to meet the Paris target, even when accounting for

**Figure 22.4: Global CO<sub>2</sub> emissions and associated global mean temperature increase for the SSP2 baseline and derived scenarios consistent with the Paris target to stay well below 2°C increase**

Source: IEA (2017); Riahi *et al.* (2017); Rogelj *et al.* (2018).

negative emissions (see Figure 22.5). There are various ways to reach these targets. While demand-side measures mostly reduce energy intensity, supply-side measures would increase the share of low-carbon options. These two indicators can provide an insight into the challenge that such reductions would pose.

The final energy-intensity (energy divided by GDP) reduction rate in many countries has typically been around 1-2 per cent

**Figure 22.5: 2010-2050 energy intensity reduction rate and the 2050 share of low-greenhouse gas technologies in total energy mix of the scenarios included in the SSP database**

**Figure 22.6: Different pathways leading to a global mean temperature increase well below 2°C**

Source: Bauer *et al.* (2017); Riahi *et al.* (2017).

on lifestyle change (e.g. the 'consumption change' pathway), emission reductions occur primarily through a transition away from the use of airplanes and private cars to local electric public transport and fast trains.

#### Decarbonizing energy supply

A high proportion of the required emission reductions would need to come from supply-side changes (see Figure 22.6). Fossil fuels currently account for around 80 per cent of total primary energy use. This needs to be reduced to a maximum of 20-30 per cent by 2050, depending on the use of negative emission technologies (after 2050) and the ambition of the climate target (Bauer *et al.* 2017; van Vuuren *et al.* 2017b). The fossil fuels need to be replaced by low- to zero-emission technologies, such as bioenergy, other renewables and nuclear energy, and fossil fuel energy combined with carbon-capture-and-storage.

It will be very important to introduce new policies that stimulate the further penetration of renewables. The literature also shows that there is some degree of freedom in choice of technology. For instance, there can be different roles for renewable energy, nuclear power and carbon-capture-and-storage, depending on societal choices and technology development. It should be noted, however, that the size of the overall transformation is – in absolute terms and the period for which it should be sustained – without historical precedent (van der Zwaan *et al.* 2013; van Sluisveld *et al.* 2015). It is in fact well beyond the rate of transitions in the past, highlighting the considerable challenge of meeting the 2°C target (Napp *et al.* 2017). In relative terms (e.g. per cent of investment in new technologies), there are several examples of similar rapid transitions in the past.

There are many ways to decarbonize energy supply in future scenarios (Clarke *et al.* 2014; Kriegler *et al.* 2018; Rogelj *et al.* 2018). One method is fossil fuel energy combined with carbon-capture-and-storage. Most scenarios rely heavily on this option. While the advantage is that it would require relatively far change in energy supply, this option suffers from a limited storage potential and, above all, relatively little societal support. Renewables such as wind and solar power

form an important alternative. The costs of these options have decreased rapidly over the last few years, making these technologies a reasonable alternative for fossil fuels even in the absence of stringent climate policy. However, for higher levels of penetration these options suffer from additional costs related to intermittency. This implies that the expansion of renewable energy will require investment in infrastructure to deal with intermittency (e.g. via expanding grid connections and providing storage options). The transition to renewables would also lead to a change in demand for materials (to create solar and wind power plants). Most assessments find the latter not being restrictive (Arvesen *et al.* 2018). Finally, a transition to renewables will also require different operating regimes for the power system. The option of bioenergy could also be attractive as a supply for fuels and, in combination with carbon storage, a pathway to negative emissions. As bioenergy requires large amounts of land it would, however, compete with the targets

#### Box 22.2: Contribution of land-use-based mitigation options to climate policies

About 20-30 per cent of total greenhouse gas emissions are associated with agricultural activities (Smith *et al.* 2014). In terms of climate policy, the contribution of the land-use sector is very important. First of all, reaching stringent targets would require reducing land-use-related emissions. In addition, it is also possible to contribute to emission reductions by so-called land-use-related mitigation options. This includes, for instance, reforestation and the use of bioenergy. In fact, more than 80 per cent of the nations that are signatories to the Paris Agreement plan to use land-use-related mitigation options to fulfil their Nationally Determined Contributions (NDCs). Analysis has shown that both afforestation and the use of bioenergy in combination with carbon-capture-and-storage are cost-efficient in nearly all scenarios. As a result, the use of land for mitigation might in 2050 be in the order of 25-30 per cent of total cropland in some scenarios (i.e. 10 per cent of total agricultural area). An important challenge, however, is that the use of land-use-based mitigation options could lead to significant trade-offs with the targets to end hunger and preserve biodiversity, due to competition for land (see Section 22.3.1).

mentioned in the previous cluster. This is discussed further in Section 22.4.2. Alternative pathways that rely less on negative emission technologies could be based on stronger changes in lifestyle (van Vuuren *et al.* 2018). Finally, nuclear power can also provide zero-emission energy. However, this technology poses both safety and waste risks and a lack of societal support in many countries.

#### Reducing non-CO<sub>2</sub> emissions

Although carbon dioxide forms the lion's share of greenhouse gas emissions, non-CO<sub>2</sub> greenhouse gases such as methane, nitrous oxide and fluorinated greenhouse gases also contribute significantly to climate change. Thus, non-CO<sub>2</sub> emissions in pathways that limit global warming to the Paris targets also show deep reductions (IPCC 2018). Some of the non-CO<sub>2</sub> emissions are relatively easy to abate, such as those associated with losses in the energy system. Moreover, these reductions often have high co-benefits including the reduction of methane (also leading to ozone pollution) and soot (leading to climate change and health impacts). In contrast, other sources are relatively hard to abate. For instance, it is hard to imagine how methane emissions from roaming cattle could be reduced to zero. As a result, in most 2°C scenarios, land-use-related emissions are reduced by around 50 per cent compared with current emission levels. Reducing emissions further would typically require reduced meat consumption (see Section 22.3.1).

#### Controlling air pollution

Future air pollution emissions stemming from human activities, with the energy sector playing a dominant role, require the application of specific measures to reduce air pollutant emissions. Many of the strategies that decrease greenhouse gas emissions, such as increasing energy efficiency, switching fuel types and changing lifestyles, also lower emissions of other air pollutants, resulting in health co-benefits (Markandya *et al.* 2018). Similarly, air pollution policies have climate implications, for example, by affecting emissions of short-term climate forcers such as black carbon.

To explore the limit on what air pollution emission decreases might be possible by introducing air pollution control measures, Stohl *et al.* (2015) defined a maximum technologically feasible reductions scenario by applying the lowest emission rates from known technology regardless of costs. Other scenarios have taken costs and local circumstances into account, such as the 'new policy' and 'clean air' scenarios of the International Energy Agency (IEA 2016). While the 'new policy' scenario considers policies and measures that had been adopted or announced as intended (as of 2015), the 'clean air' scenario includes additional measures that achieve significant reduction of air pollutant emissions. Relative to the 'new policy scenario', the 'clean air' scenario includes an additional US\$2.3 trillion invested in advanced air pollution control technologies and a similar amount (US\$2.5 trillion) invested in accelerating the transition to cleaner and renewable energy sources. These measures would result in a 50 per cent decrease in SO<sub>2</sub> and NO<sub>x</sub> emissions and an almost 75 per cent decrease in particulate matter emissions and would avoid more than 3 million premature deaths per year, with 1.7 million deaths attributable to reduced ambient air pollution and 1.6 million deaths attributable to reduced household air pollution (IEA 2016).

The importance of climate mitigation for air pollution emissions can also be illustrated using SSP results (Rao *et al.* 2017): increasingly stringent climate policy also reduces emissions of air pollutants. The extent to which coal is used for electricity production and manufacturing has a strong influence on CO<sub>2</sub> emissions and largely determines the path of SO<sub>2</sub> emissions. For transportation sector emissions, the level of electrification is important. Electrification, combined with autonomous vehicles and shared mobility services, could lead to dramatic decreases in emissions and associated pollutant exposures (Fulton, Mason and Meroux 2017). Black carbon emissions, associated with diesel engines and residential combustion of traditional biomass fuels, are much less correlated with fossil fuel use (and thus climate policy), but more with use of traditional energy (and thus with the introduction of access to modern energy services); this is reflected in the different black carbon emission levels for the baselines, but also in a much lower response to climate policies (Rao *et al.* 2017).

Short-lived climate pollutants (SLCPs) contribute to atmospheric warming, and include black carbon, tropospheric ozone, methane and hydrofluorocarbons. Among SLCPs, black carbon, methane and tropospheric ozone contribute to air pollution. Reducing emissions of SLCPs can provide near-term climate benefits (Shindell *et al.* 2017; Xu and Ramanathan 2017; Haines *et al.* 2018). For black carbon, measures are available to decrease emissions from diesel engines, biomass cooking fuel, kerosene lighting, and household and small industry coal use. There are opportunities to decrease methane emissions associated with the extraction of coal, oil and natural gas, disposal of waste, switching management of emissions from livestock and manure and rice paddy production. Compliance with the Kigali Amendment (United Nations 2016) will decrease hydrofluorocarbon emissions by 61 per cent from 2018 to 2050 compared to a reference scenario, but substitutions could be made earlier and a 98 per cent decrease is technically possible (Höglund-Isaksson *et al.* 2017). Implementation of such demonstrated technical measures to address SLCP could decrease average global warming, although estimates on the exact level differ by study (United Nations Environment Programme [UNEP] 2017) (see also **Box 22.3**).

## Box 22.3: The Climate and Clean Air Coalition

Efforts to simultaneously address air quality and climate impacts of short-lived climate pollutants (SLCPs) include the Climate and Clean Air Coalition (CCAC; <http://www.ccacoalition.org>), which was launched in 2012 and is a voluntary partnership of governments, intergovernmental organizations, businesses, scientific institutions and civil society organizations committed to improving air quality and mitigating climate change by reducing SLCPs. Approaches for reducing black carbon include clean and efficient household cooking, lighting and heating technologies; modern brick kiln technology for brick production; and clean fuel for heavy-duty diesel vehicles and engines. The focus for reducing methane emissions includes reducing gas leakage from gas distribution systems, improving manure management, using alternative rice farming practices and strategies to reduce enteric fermentation emissions from livestock. As of July 2017, some 178 countries had included methane, 100 had included hydrofluorocarbons, and four had included black carbon in their Nationally Determined Contributions (NDCs) or Intended NDCs for meeting the climate goals of the Paris Agreement. A number of countries are expected to update their NDC to strengthen the inclusion of SLCPs. It is important to note that reducing emission of SLCPs as a complement to reducing greenhouse gas emissions provides opportunities to limit near-term climate warming but is not a substitute for reducing long-lived greenhouse gases to mitigate long-term climate change.

22

**Figure 22.7a: Projected global emissions for SO<sub>2</sub>, NO<sub>x</sub> and black carbon under different climate and air pollution policies**

For the SSP baselines the shading represents the ranges over all Integrated Assessment Models (IAMs) included in Rao et al. (2017).

Source: SSPs (Rao et al. 2017); ECLIPSE (Stohl et al. 2015; Klimont et al. 2017); IEA (IEA 2016).

**Figure 22.7b: Differences in air pollution emissions between various climate mitigation scenarios, and the SSP2 baseline**

Error bars represent the range of all Integrated Assessment Models (IAMs) included in Rao et al. (2017).

Source: Rao et al. (2017).

Although climate policies lead to significant decreases in air pollution in all SSP marker scenarios, these decreases are not sufficient to achieve the WHO air quality guideline of  $10 \mu\text{g}/\text{m}^3$  for annual mean  $\text{PM}_{2.5}$  concentrations by 2050 (**Figure 22.8**). The ECLIPSE maximum technically feasible reduction (MTFR) scenario without climate mitigation, which has the lowest air pollutant emissions among all scenarios (**Figure 22.7**), is also insufficient to achieve the WHO guideline. Worldwide, about 60 per cent of the population is projected to be exposed to levels above the standard in the best-case air pollution scenarios (SSP1 or SSP5 with  $2.6 \text{ W}/\text{m}^2$  climate mitigation target, or the ECLIPSE MTFR scenario). The worst exposures are projected for Asia and the Middle East and Africa regions. However, by 2050 less than 5 per cent is expected to be above the most lenient interim target of  $35 \mu\text{g}/\text{m}^3$  annual mean  $\text{PM}_{2.5}$  concentrations for SSP2 and SSP5 if climate mitigation is included. These results reflect the air quality benefit of strong air pollution control and the co-benefit of climate mitigation, and for the ECLIPSE MTFR scenario, reflecting the maximum air quality benefit achievable with current air pollution control technologies.

### **Significant synergies and trade-offs between measures and targets**

The measures introduced to achieve universal access to modern energy services, combat climate change or improve air quality in cities can have important synergies and trade-offs (e.g. McCollum *et al.* 2018).

- ❖ Most of the climate policies lead to an increase in energy system costs, with potentially increasing energy prices as a result. Higher energy prices, especially for clean fuels for cooking (e.g. electricity, liquified petroleum gas, natural gas), make it more difficult to achieve universal energy access, or to provide affordable energy in general (Daiglou, van Ruijven and van Vuuren 2012; Cameron *et al.* 2016). There are, however, various ways to compensate for this, including targeted subsidies or redistribution of carbon taxes (Cameron *et al.* 2016).
- ❖ Policies aiming to increase energy access could lead to an increase in energy consumption and thus impact both climate change and air pollution. These impacts, however, are relatively small (van Vuuren *et al.* 2012) and can, if needed, be mitigated by ensuring that energy access is achieved via low-greenhouse gas energy supply systems. Achieving universal electricity access is estimated to have only a very small increasing effect on global greenhouse gas emissions (Pachauri *et al.* 2013; van Vuuren *et al.* 2015; Dagnachew *et al.* 2018). Furthermore, universal access to clean fuels for cooking could reduce total air pollutant and greenhouse gas emissions, resulting from a switch away from traditional biomass, increased biomass-use efficiency and sustainable harvesting of biomass (Pachauri *et al.* 2013; van Vuuren *et al.* 2015). There are also both synergistic effects and trade-offs between air pollution and climate policy. One example of a possible trade-off is that burning biomass as a low-carbon energy source can lead to more air pollution if appropriate air quality management practices are not put in place (Giuntoli *et al.* 2015). Another is that diesel cars emit less  $\text{CO}_2$  than petrol (gasoline) cars but emit more PM (Mazzi and Dowlatabadi 2007; Tanaka *et al.* 2012; O'Driscoll *et al.* 2018). Also, the use of end-of-pipe emission controls may reduce PM emissions of passenger vehicles, but at the cost of reducing fuel efficiency. For petrol vehicles, replacing port fuel injection with direct injection engine technology generally increases fuel efficiency, thus reduces  $\text{CO}_2$  emissions, but increases PM and black carbon emissions (Zhu *et al.* 2016; Zimmerman *et al.* 2016; Saliba *et al.* 2017).
- ❖ However, in most cases, climate policy reduces air pollution by having an impact on emissions of PM,  $\text{SO}_2$  and  $\text{NO}_x$ . If well designed, air pollution control measures can also limit climate change. This implies that especially for countries currently experiencing high air pollution levels, designing strategies that address both air pollution and climate change can be very attractive (see also **Box 22.4**).
- ❖ Geo-engineering (e.g. direct air capture) generally requires additional energy use providing a possible trade-off with air pollution or energy access.

### **Box 22.4: Possible synergy between climate mitigation and reducing air pollution in China**

In response to strong public concerns about air pollution, the China State Council announced in 2013 the 'Action Plan of Prevention and Control of Air Pollution'. The action plan sets specific targets for air pollution. Among others, the 2017 concentration of particulate matter with diameter less than  $10 \mu\text{m}$  ( $\text{PM}_{10}$ ) should fall by at least 10 per cent compared to 2012 concentrations. For some regions, however, more stringent targets are formulated. The plan indicates that one way to implement these targets is through promotion of clean energy, including renewable energy, nuclear power, natural gas, combined with a transition of the energy system, energy conservation and control of coal use. This is completely consistent with low-carbon development in China. Since then, the economic and structural changes together with air pollution control measures resulted in a peak in coal production in 2013/2014. This has also led to a reduction of  $\text{CO}_2$  emissions. From 2015 to 2017, there was a rapid expansion of wind, solar and hydro power as well as nuclear power. If, in the future, the increase in energy demand is relatively slow, any expansion can be covered by the increase in renewable energy, nuclear and natural gas, so that the decline in coal capacity can continue. Under these circumstances, a further decline of  $\text{CO}_2$  emissions is possible. In the meantime, sustainable development is a basic long-term national strategy in China. China has started to enhance its energy efficiency policies in its Eleventh Five-Year plan and is expected to continue to do so in subsequent Five-Year plans. The main focus for these policies will continue to be on improving energy efficiency in the industrial sector, but new policies are also targeting domestic energy consumption. On this basis, the target is to reduce the share of coal in the energy mix from 64 per cent in 2015 to 58 per cent in 2020. According to the announcement of "Interim measures of the replacement of coal consumption in key regions" from China's National Development and Reform Commission (NDRC *et al.* 2014), 8 provinces and municipalities in key areas, including Beijing-Tianjin-Hebei Region, Shandong province, the Yangtze River Delta and the Pearl River Delta will be required to set up the reduction targets for coal consumption. These policies are meant to reduce air pollutants. All-in-all, it means that current Chinese policies to improve air quality could have a huge benefit for public health, but also lead to a reduction of  $\text{CO}_2$  emissions.

**Figure 22.8: Percentage of the population exposed to particulate matter of less than 2.5  $\mu\text{m}$  in diameter ( $\text{PM}_{2.5}$ ) concentrations under the WHO guideline and interim target for 2050**

Sources: Rao *et al.* (2017); Population exposure is based  $\text{PM}_{2.5}$  concentrations determined by applying the TM5-FASST source-receptor model (van Dingenen *et al.* 2018) to marker SSP emission scenarios and the related 4.5  $\text{W}/\text{m}^2$  and 2.6  $\text{W}/\text{m}^2$  climate mitigation scenarios.

### 22.3.3 Freshwater

The selected targets for the freshwater cluster may be summarized as reducing water scarcity and ensuring water quality, while at the same time providing universal access to safe drinking water and adequate sanitation (Chapter 20). The world is not on track to achieve these targets (see Chapter 21). More than 400 million people are projected to still lack access to at least basic water facilities in 2030 and about 2 billion people still do not have access to at least basic sanitation. Furthermore, the fraction of the global population that lives in water-stressed areas is projected to increase up to about 50 per cent by the end of the century, mostly driven by population growth.

There are important linkages between this cluster and other clusters, especially the agriculture, food, land and biodiversity cluster and the energy, air and climate cluster. Globally, the largest demand for water comes from the agricultural sector (over 70 per cent). Also, many freshwater and ocean pollutants come from agriculture, and agriculture is the dominant source of nitrogen and phosphorus in global watersheds (see Chapter 21).

There are several scenario studies on water scarcity. However, most of these focus on future projections instead of target-based scenarios. In contrast, Wada, Gleeson and Esnault (2014) propose six strategies, or 'water-stress wedges', that collectively lead to a reduction in the water-stressed population by 2050. Bijl *et al.* (2018) discuss some strategies that could

lead to reduced water scarcity, including increased efficiency, other allocation strategies and reducing agricultural water demand via diet change and food waste reduction. Here, we discuss different measures largely linked to the individual targets, addressing increasing access to water, sanitation and hygiene (WASH), decreasing water demand, increasing water supply and reducing water pollution.

### **Investing in access to water, sanitation and hygiene**

Achieving the targets on drinking water and sanitation will require increased investment in infrastructure, especially sanitation (United Nations Conference on Trade and Development 2014; Hutton and Varughese 2016). Due to population growth, an additional 3.4 billion people will require access to sanitation by 2030, or 620,000 per day, 2.5 times the number of people served during the 2001-2015 period (Mara and Evans 2018). The current levels of investment are likely to cover the capital costs of basic service provision for access to WASH by 2030, but not enough for safely managed service provision. To achieve universal access to safely managed WASH services, investment levels will need to increase threefold (Hutton and Varughese 2016). Achieving universal access to safe water and adequate sanitation is as much about changing behaviour as it is about changing infrastructure. This requires better marketing, communication and community-led sanitation (Water and Sanitation Program 2004; Kar and Chambers 2008; Devine and Kullmann 2011).

### **Increasing water-use efficiency**

Water scarcity including groundwater often needs to be managed at the watershed or aquifer level (Scott *et al.* 2014). These can be within one country, but often there are multiple countries involved. In those cases, an international framework is needed to evaluate strategies to reduce water stress and maximize mitigation (Wada, Gleeson and Esnault 2014). Wada, Gleeson and Esnault (2014) conclude that four demand-side measures are required: increasing agricultural water productivity (more crop per drop), improving irrigation efficiency (reducing water losses), more efficient water use in domestic and industrial sectors including reducing water leakage and improving recycling, and limiting the rate of population growth. To maintain or even reduce the global population under water scarcity by 2050 and beyond, water-use efficiency for these demand-side measures needs to improve by more than 20-50 per cent globally (0.5-1.2 per cent improvement per year). Moreover, strategies for water management at the level of watersheds are necessary to deal with competing demands for agricultural production, industrial activities, household water use and ecological services. The precise mix depends on economic, social, legal and political issues such as international or subnational water treaties, rights or disputes (Wada, Gleeson and Esnault 2014). Various scenarios have shown that increased water efficiency in agriculture, households and industry can have a significant impact on reducing water scarcity (e.g. Bijl *et al.* 2017).

### **Increasing water supply**

Increasing water supply can be done using more conventional measures such as building more water storage or dams, by investing more in desalination capacity in coastal regions (Wada, Gleeson and Esnault 2014) or by wastewater reuse. Furthermore, groundwater resources could serve as a buffer during droughts or severe water scarcity because of their ubiquitous presence across the globe.

Increasingly, countries are implementing desalination strategies – for example, in the Middle East, North Africa and the United States of America (e.g. California) (World Water Assessment Programme 2003; Hanasaki *et al.* 2016). The global amount of desalinated water use has been rapidly increasing since the 1990s and it is currently estimated to exceed 10 km<sup>3</sup> annually (Food and Agriculture Organization of the United Nations 2018). Although this amount is important for coastal regions, the global total currently accounts for much less than 1 per cent of water withdrawals worldwide (4,000 km<sup>3</sup>). Hanasaki *et al.* (2016) projects that under different SSP scenarios (1-3), the use of seawater desalination will increase 1.4- to 2.1-fold in 2011-2040 compared with the present, and 6.7- to 17.3-fold in 2041-2070. The associated costs are in the order of US\$2 billion to US\$200 billion. The large spreads in these projections are primarily attributable to substantial socioeconomic variations in the SSP scenarios. To scale up desalination of seawater in coastal water-stressed basins, a 10- to 50-fold increase is projected to be required; however, this would imply significant capital and energy costs, and it would generate wastewater that would need to be disposed of safely (Wada, Gleeson and Esnault 2014; Hanasaki *et al.* 2016).

Wastewater reuse enables upgrading of unsuitable water quality originating from households and industry to sufficient quality for different purposes. The amount of wastewater reuse or recycling has been increasing worldwide especially for agriculture, as small-scale farmers in urban and peri-urban areas of developing countries depend largely on wastewater or wastewater-polluted water sources to irrigate high-value crops for market (Qadir *et al.* 2010). However, higher-quality water is needed for drinking purpose and the establishment of water reuse guidelines is critical (Bixio *et al.* 2006; Bixio *et al.* 2008). Ongoing technological innovations, such as the use of membranes, and dedicated economic instruments are expected to further increase the use of wastewater as a resource in various regions with limited surface- and groundwater resources. In order to reduce water limitations in urban areas or megacities, a similar magnitude of future scaling up is required for wastewater reuse combined with the desalination of seawater (Wada, Gleeson and Esnault 2014).

It should be noted, however, that these two supply-side measures require a large amount of economic investment and modernizing of existing infrastructure, which might not be feasible for many developing countries (Neverre, Dumas and Nassopoulos 2016). Alternatively, nature-based solutions may have high potential to increase and/or regulate water supply by reducing degradation of water quality, while limiting economic investments (Vörösmarty *et al.* 2010). Multiple ecosystem services or sustainable infrastructure can mitigate water pollution and increase water supply for humans and ecosystems (Reddy *et al.* 2015; Lique *et al.* 2016). These examples highlight an important role for development and deployment of water conservation technologies and practices to achieve water-related SDG targets (Hejazi *et al.* 2014).

### **Reducing water pollution**

Experience in developed countries has shown that it is possible to reduce water pollution. Unfortunately, there is very little scenario literature addressing water pollution problems and ways to achieve future sustainability targets. However, there is some literature discussing reduced nutrient pollution,

for example by wastewater treatment. A global decrease in nutrient discharge is possible only when wastewater treatment plants are extended with at least tertiary treatment in developing countries and with advanced treatment in developed countries. Separate collection systems for urine can reduce nutrient pollution to 15TgN/yr and 1.2TgP/yr (van Puijenbroek, Beusen and Bouwman 2019). When all effluent from sewage systems receive tertiary treatment, global nutrient discharge is projected to decrease to 1990 levels (Ligtvoet *et al.* 2018). For phosphorus, a further decrease could be realized when all laundry and dishwasher detergents are phosphorus-free. This is now mandatory in the European Union, United States of America, Japan and some other countries.

Increasing crop yields and fertilizer-use efficiencies will have a direct effect on the nutrient loading of streams and rivers. However, starting from a situation of low crop yields and minimal nutrient inputs, nutrient loading of watersheds may well increase in scenarios with a shift towards food production systems now prevalent in industrialized countries. Since watersheds retain nitrogen and phosphorus, there may be legacies of past management. As a consequence, nitrogen concentrations in many rivers respond only slowly to increased nitrogen-use efficiency in food production. For example, due to these legacies, European water quality is threatened by rapidly increasing nitrogen-phosphorus ratios (e.g. Romero *et al.* 2013). Developing countries can avoid such problems by managing both nitrogen and phosphorus, accounting for residual soil phosphorus, while avoiding legacies associated with the past and continuing mismanagement of high-income countries.

#### **Significant synergies and trade-offs between measures and targets**

A number of synergies and trade-offs can be identified between specific measures and the various targets within this cluster. A few important ones are as follows.

- ❖ Increased access to and use of improved and safely managed WASH facilities has direct health benefits and can also improve overall quality of life. Women in developing countries often travel long distances to access water and sanitation facilities, even more so than men because of domestic-related tasks that more often fall to women, and because of menstrual hygiene (Pommells *et al.* 2018). Not only does this leave women more susceptible to health risks from more frequent contact with unsafe facilities, but there is a growing body of literature on the prevalence, and lack of documentation, of assault and rape on these trips (Sorenson, Morssink and Campos 2011; Watt and Chamberlain 2011; Sahoo *et al.* 2015; Sommer *et al.* 2015; Freshwater Action Network South Asia and Water Supply and Sanitation Collaborative Council 2016; Pommells *et al.* 2018).
- ❖ Increased levels of access to at least basic safe drinking water and adequate sanitation can drive increased domestic water demand, further contributing to water stress (Hanasaki *et al.* 2013a; Hanasaki *et al.* 2013b; Wada *et al.* 2016).
- ❖ Water scarcity negatively affects agriculture and biodiversity and also energy supply. In fact, water stress is one of the five global risks of highest concern according to the World Economic Forum (Wada, Gleeson and Esnault 2014).

- ❖ Agriculture is the dominant source of nutrients in global watersheds leading to eutrophication, resulting in hypoxia symptoms in many inland and coastal areas. There is a tendency towards increasing nitrogen-phosphorus ratios and declining silica; this distortion of nutrient ratios leads to the proliferation of harmful algal blooms, both in global watersheds and coastal parts of oceans.
- ❖ Improved sanitation facilities without, or with only primary, wastewater treatment are major polluters of freshwater, due to nitrogen and phosphorus discharge (van Puijenbroek *et al.* 2015).
- ❖ While the only option for some water-scarce communities, desalination is very energy-intensive, potentially counteracting interventions to reduce industrial water demand (Pinto and Marques 2017).

#### **22.3.4 Oceans**

The selected targets for the oceans cluster are limiting ocean acidification, reducing nutrient pollution and sustainably managing ocean resources (see Chapter 20). For all three targets, trends are projected to go in the wrong direction (see Chapter 21). There is strong evidence that the current trend towards declining fish populations and reduced species richness impair the ecological functioning of oceans, including their role in providing food (Worm *et al.* 2006). Nutrients from fertilizers used to increase agricultural yields have also found their way into nearly every water body across the globe where they stimulate aquatic plant production. As a consequence, hypoxia, a growing global problem, occurs where organic matter decay consumes oxygen faster than its diffusion from the oxygen-rich surface. Furthermore, the global problem of harmful algae is now on a pathway of more and more frequent blooms, in more places and with increasing severity, with more toxins (Glibert 2017).

Pathways in this cluster are largely linked to developments in other clusters. With respect to ocean acidification, the scenario literature is linked to climate change (i.e. the reduction of CO<sub>2</sub> emissions; Section 22.3.2), marine nutrient pollution with agricultural production measures (Section 22.3.1) and freshwater pollution (Section 22.3.3). Here, we discuss different measures linked to the individual targets, addressing ocean acidification measures and sustainable ocean management. No scenario studies were found that address the reduction of marine nutrient pollution to stop related hypoxia and harmful algal blooms.

#### **Ocean acidification measures**

Ocean acidification is a result of the increased absorption of CO<sub>2</sub> in the oceans, which in turn is a result of an increasing global atmospheric CO<sub>2</sub> concentration. Billé *et al.* (2013) identify three means of preventing ocean acidification:

- i. reducing CO<sub>2</sub> concentrations, either by lowering emissions or removing CO<sub>2</sub> from the atmosphere, for example through carbon-capture-and-storage under the seabed (see Section 22.3.2);
- ii. limiting ocean warming; and
- iii. reducing nutrient run-off into the ocean.

Furthermore, they identify means of reversing acidification after it has occurred, including additives (e.g. alkalization) and ecological restoration.

Reducing emissions of CO<sub>2</sub> thus reduces ocean acidification directly, while other climate policy measures can have an indirect effect via reducing sea surface temperature. For example, Mora *et al.* (2013) find less reduction in ocean pH and ocean productivity in Representative Concentration Pathway (RCP) 4.5 than in RCP 8.5. Similarly, Bopp *et al.* (2013) find a decline in ocean pH of only 0.07 and an increase in sea surface temperature of only 0.71°C in a stringent climate policy scenario, compared with a decline in pH of 0.33 and an increase in sea temperature of 2.73°C in a high-emission scenario. In fact, carbonate ion concentrations do not fall below saturation levels in the stringent climate policy scenario for any ocean (Bopp *et al.* 2013). Concentrations below saturation level can lead to dissolution of shells and skeletons of marine organisms.

### **Sustainable ocean management**

Currently, fisheries worldwide are severely degraded as a result of overfishing. Several scenarios have looked at the impact of strong fisheries management (among others through the reduction of catch) to find that there could be a decrease in the proportion of exploited fish stocks to close to a recovery target biomass. This would, in the long run, also mean an increase in total global fisheries profit, relative to both the trend scenario and even the present day. Costello *et al.* (2016) analysed data excluding small-scale and artisanal fisheries but representing 78 per cent of global catches and found that applying management policies for returning catch to maximum sustainable yield or even maximum profits through rights-based fisheries management was projected to produce improvements in catch profit, and fish stock biomass relative to the business-as-usual management scenario. By 2050, some 98 per cent of stocks could be biologically healthy under strong fisheries management (Costello *et al.* 2016).

Similarly, under a low-greenhouse gas emissions scenario, Lam *et al.* (2016) projected a smaller decline in catch potential (4 per cent versus 7 per cent in the trend scenario), suggesting that climate policy can limit the impacts of climate change on global fisheries. Also, Cheung, Reygondeau and Frölicher (2016) estimated the benefits to global fisheries from meeting the 1.5°C warming target in the Paris Agreement: every degree of warming above this target resulted in a projected 3 million (metric) tons reduction in potential catch.

Another way to promote more sustainable fisheries and protect biodiversity is by introducing protected areas (Agardy 2000). Marine protected areas tend to increase the biomass of fish (Gill *et al.* 2017), but there is debate about the effectiveness of marine protected areas for biodiversity (Worm *et al.* 2006; Edgar *et al.* 2014). The effectiveness of protected areas regimes depends strongly on their management and enforcement (Edgar *et al.* 2014; Gill *et al.* 2017). In addition, by introducing better strategies for selecting protected areas, their impact can be increased significantly (Davis *et al.* 2017). However, similar to protection of terrestrial biodiversity, it is clear that for preventing biodiversity loss, increasing protected areas will not be enough (Mora and Sale 2011).

### **Significant synergies and trade-offs between measures and targets**

A number of synergies and trade-offs can be identified between specific measures and the various targets within this cluster. A few important ones are as follows.

- ❖ Reviving current fish stocks will require a period of reduced catches, therefore potentially reducing the contribution of fish resources in reducing hunger. However, as shown, in the long run this will lead to higher sustainable yields.
- ❖ Reduced marine nutrient pollution could make coral reefs less vulnerable to ocean acidification and reduce the predicted shift from net accretion to net erosion (Silbiger *et al.* 2018).
- ❖ Reducing ocean acidification by means of limiting CO<sub>2</sub> emissions is also important to conserve marine biodiversity and to secure the availability of fish resources to reduce hunger worldwide.

### **22.3.5 Human development**

The selected target for the human development cluster is ending preventable deaths of children under five years of age (see Chapter 20), with the acknowledgement that other environmental health impacts and age groups are also relevant for human health (see also Section 20.3.1). For example, exposure to ambient PM<sub>2.5</sub> was the fifth-ranking mortality risk factor in 2015 (Cohen *et al.* 2017; Chapter 5) and the deadliest of any environmental risk factor. More than half of the premature deaths attributed to ambient air pollution occur among those older than 50 years of age, while household air pollution, the second highest environmental risk factor, predominantly affects children and women (GBD 2016 Risk Factors Collaborators 2017; see also Section 5.3.1). Future projections show a reduction in the global child mortality rate, but not enough to achieve the target, while air pollution is projected to continue to contribute to millions of premature deaths annually (Chapter 21).

There are strong links between the child mortality target and several other targets discussed in this chapter. Important health risk factors affecting under-five mortality rates include malnutrition (strongly related to hunger), no access to safe drinking water, adequate sanitation and hygiene (WASH), indoor air pollution and (more indirectly) also climate change.

There are very few studies that look at reducing child mortality in relation to a range of environmental risk factors (e.g. Hughes *et al.* 2011; Lucas *et al.* 2018). Most studies focus on individual risks, most prominently malnutrition (i.e. prevalence of undernourishment) and ambient air pollution. Ending preventable death of children under five, especially with respect to environmental health risks, largely depends on achieving specific targets discussed for the other clusters in this chapter. However, pathway studies suggest that a healthy planet alone is not enough for achieving healthy people (Hughes *et al.* 2011; van Vuuren *et al.* 2015; Lucas *et al.* 2018; Moyer and Bohl 2018). The success of the different pathways in reducing child mortality depends on the degree to which they also address non-environmental risk factors, reducing both wealth inequalities and social inequalities. Here, we discuss four broad measures – reducing exposure to environmental risk factors, poverty alleviation, women and girl's education, and child and maternal health care.

### **Reducing exposure to environmental risk factors**

Preventable risks for children under five include malnutrition (e.g. child underweight), exposure to fine particulate emissions causing pneumonia, and micropathogens and vectors that can transmit infectious diseases such as diarrhoea and

malaria. Climate change can negatively impact several of these risk factors, including child underweight (Hughes *et al.* 2011) and malaria (Craig, Snow and le Sueur 1999). Measures for reducing exposure to related risk factors are extensively discussed in Sections 22.3.1 to 22.3.3. Here, we repeat some of these measures and discuss overall impacts on child mortality.

For ending malnutrition (SDG target 2.1), interventions include increased food availability through (for example) yield improvement, diet changes and waste reduction, as well as improving access to food and nutrition management for the poor (Section 22.3.1). Reduced consumption in high-income countries does not necessarily increase availability and access for poor communities and therefore has a low impact on reducing malnutrition and related child mortality (Moyer and Bohl 2018). A combination of availability and access measures are thus required. For reducing air pollution (SDG target 11.6), interventions include introducing effective air pollution controls, cleaner vehicles, better public transport and encouragement of active modes of transport via easily accessible walkways and bicycle paths, and finally reduced household air pollution through improved access to cleaner fuels and cookstoves (SDG target 7.1) (Section 22.3.2). For children under five, improving indoor air pollution through a transition away from traditional biomass on open fires or traditional stoves can result in significant health benefits. Finally, interventions to reduce exposure to microbial pathogens include increased levels of access to and knowledge of safe water, safely managed sanitation and hygiene (SDG targets 6.1 and 6.2) (Landrigan *et al.* 2018, p. 40) (Section 22.3.3).

Through interventions on all three risk factors, the environmental risks of under-five mortality are lessened, leading to reduced mortality from malnutrition, diarrhoea, pneumonia and other common infectious diseases (e.g. malaria). However, even if all the related environmental SDG targets were achieved by 2030, the under-five mortality target would not be met (Hughes *et al.* 2011; van Vuuren *et al.* 2015; Lucas *et al.* 2018; Moyer and Bohl 2018). Lucas *et al.* (2018) show that achieving health-related SDG targets on child nutrition, access to improved drinking water and sanitation, and access to modern energy services can avoid globally around 440,000 child deaths in 2030, reducing projected 2030 global under-five mortality by around 8 per cent. Hughes *et al.* (2011) conclude that, between 2005 and 2060, some 131.6 million cumulative child deaths (23 per cent of total deaths related to communicable diseases) could be avoided by gradually reducing childhood underweight, unsafe water, poor sanitation and hygiene, indoor air pollution and global climate change.

### **Alleviating poverty**

There is considerable overlap between poor health and poverty (Aber *et al.* 1997; Yoshikawa, Aber and Beardslee 2012). In fact, while poverty is generally indicated as a measure of income, it can also be defined in terms of relative deprivation in a range of capabilities, including good health, but also higher levels of education (Hulme and Shepherd 2003; Alkire 2007). Poverty as defined by low income negatively impacts both health and education outcomes driving further deprivation (Hulme and Shepherd 2003). Conversely, eradicating extreme poverty (SDG target 1.1), and thereby improving the income situation of poor households, can improve health, especially of children under five.

### **Women and girl's education**

Inclusive and equitable quality education (SDG 4), especially of women, is highly correlated with reduced child mortality. Furthermore, higher levels of education are associated with better overall health, lower fertility rates, increased economic growth, reduced poverty levels and more democracy (Dickson, Hughes and Irfan 2010; Lutz and Samir 2013; Dickson, Irfan and Hughes 2016). Over half the decline in child mortality from 1970 to 2009 can be attributed to increased education of women of reproductive age (Gakidou *et al.* 2010). Lucas *et al.* (2018) show that through a comprehensive strategy that includes universal female education, piped drinking water, a complete phase-out of biomass use for cooking and advanced malaria control, 777,000 child deaths can be avoided in 2030, reducing the projected 2030 global child mortality rate by around 13 per cent. The largest health gains are projected for sub-Saharan Africa.

### **Child and maternal health care**

Reducing child mortality is inseparable from reducing maternal mortality – a healthy life begins with a healthy mother and a healthy birth. Reducing child mortality thus also requires addressing other SDG targets, including reducing maternal mortality itself (SDG target 3.1), increasing access to family planning and reducing the adolescent birth rate (SDG target 3.7), achieving universal health coverage (SDG target 3.8) and registering all births with a civil authority (SDG target 16.9) (United Nations Children's Fund [UNICEF] 2015; WHO and UNICEF 2017). Increased contraceptive use in developing countries has reduced the maternal mortality ratio by 26 per cent over the last decade by reducing unintended pregnancies and could reduce it by another 30 per cent if the unmet need is met (Cleland *et al.* 2012). Further, access to modern contraception directly reduces child mortality because increasing the interval between pregnancies reduces likelihood of prematurity and low birthweight, and infants with siblings less than two years old have a higher likelihood of death (Cleland *et al.* 2012).

### **Synergies and trade-offs between measures and socioeconomic developments**

Apart from the obvious improvements to quality of life for people across the globe, improving health outcomes can also have significant impacts on demographics (Lee 2003; Hughes *et al.* 2011) and economic development (van Zon and Muysken 2003; Bloom, Canning and Sevilla 2004; Ashraf, Lester and Weil 2008; Suri *et al.* 2011).

- ❖ Reductions in child mortality are typically followed by fertility rate reduction, with a lag of about ten years (Angeles 2010; Bohl, Hughes and Johnson 2016). This has transformative implications (i.e. a larger working-age population followed by an ageing population) for the demographic structure of regions such as sub-Saharan Africa and South Asia, which currently have relatively high rates of both under-five mortality and fertility (Bohl, Hughes and Johnson 2016). When the working-age population growth rate exceeds that of the youth population, the growing labour force also creates economic opportunities, called the 'demographic dividend' (Bloom *et al.* 2009; Lee and Mason 2011, and see Chapter 2). During this time, fiscal burdens associated with service provision to youth (and elderly) populations are minimized, while aggregate economic productivity tends to increase (Lee and Mason

2011). However, a growing elderly population can create new budgetary constraints and more intense pressures on health and social services (Tabata 2005; Lee and Mason 2011; Bohl, Hughes and Johnson 2016; Burrows, Bohl and Moyer 2017).

- ❖ Reductions in mortality often result in reductions in morbidity of working-age populations (Hughes *et al.* 2011), further increasing aggregate economic productivity and attracting foreign investment into an economy via reduced labour-market uncertainty (Jamison *et al.* 2006; Hughes *et al.* 2011). Improved health outcomes can also lead to increased school attendance, improved cognitive skills and better educational outcomes for students (Baldacci *et al.* 2004; Soares 2006; Ashraf, Lester and Weil 2008), which improves human capital, and results in increased productivity and more healthy economies once these children move into working-age cohorts (Hughes *et al.* 2011).
- ❖ Decreased child mortality, especially when combined with female education and access to modern contraception, will likely lead to lower fertility rates in the longer term, curbing population growth, one of the major drivers of environmental degradation (Angeles 2010; Gakidou *et al.* 2010).

## 22.4 An integrated approach

In the previous sections, we discussed how to achieve a set of environment-related SDG targets (see Chapter 20 for target selection) and showed that, for many targets, pathways can be identified that could lead to meeting the targets by 2030 or 2050 – or at least result in a major improvement. Here we discuss some overall results from the analysis and a more in-depth analysis of key synergies and trade-offs between the different clusters.

### 22.4.1 Transformative change

The analysis showed that, in all areas, marginal improvements will not suffice; large, transformative changes are needed to realize the different targets, including significant improvements

in resource efficiency with respect to yields, and water-, energy- and nitrogen-use efficiency (see Table 22.1). For instance, reaching the targets related to energy access, climate change and air pollution, would imply decoupling of CO<sub>2</sub> emissions from economic growth at a rate of 4-6 per cent a year, over the coming three decades. In comparison, the same ratio only declined by 1-2 per cent a year historically, thus requiring a threefold increase of the historical rate. Furthermore, without demand-side measures, an average increase in productivity of around 1.4 per cent per year in agriculture would be needed to end global hunger, while simultaneously limiting biodiversity loss. While here the required efficiency improvements are comparable to historical improvement rates, it is clear that this will be more difficult to achieve in the future given that, in most cases, easy gains have already been implemented and agricultural production also will have to become more sustainable, including reduced water and nutrient use.

Earlier, we indicated that technological changes, lifestyle changes and multi-scale approaches are available. The measures discussed in this chapter are part of such approaches. However, given the scale of the required transition it seems far more likely that these strategies will have to be combined to achieve the level of transformation that is needed. It can also be concluded that the approaches used to unlock the available potential presented by any of these approaches has, thus far, not been very successful. The existing MEAs have not led to any break with the past (Part A and Chapter 21). It is therefore important to ensure that there is sufficient interest among actors to implement a different set of strategies. This interest is, among other influences, related to the different trade-offs and synergies of the different measures.

### 22.4.2 Synergies and trade-offs

Sections 22.3.1-22.3.5 discussed interrelations between measures and targets within the five clusters. However, there are also many synergies and trade-offs between these clusters. The SDGs and associated targets form a complicated network of interlinkages, not made explicit in their formulation (International Council for Science and International Social Science Council

**Table 22.1: Trends in resource-use efficiency: baseline (Chapter 21) versus pathways towards achieving the targets (this chapter)**

| Target                                                         | Indicator                                                                             | Baseline (Chapter 21)       | More sustainable pathways <sup>a</sup> (Chapter 22) |
|----------------------------------------------------------------|---------------------------------------------------------------------------------------|-----------------------------|-----------------------------------------------------|
| <b>Increase agricultural productivity (Section 22.3.1)</b>     | Yield improvement over time (total)                                                   | 1 per cent/year (2010-2050) | 1.4 per cent/year (2010-2050)                       |
| <b>Increase nutrient-use efficiency (Section 22.3.1)</b>       | Total N inputs to the crop N yields                                                   | 0.55 in 2050                | 0.67 in 2050                                        |
| <b>Increase water-use efficiency (Section 22.3.3)</b>          | Change in water-use efficiency over time                                              | 0.3-1 per cent (2010-2050)  | 0.5-1.2 per cent (2010-2050)                        |
| <b>Increase the share of renewable energy (Section 22.3.2)</b> | Renewable energy share in total final energy consumption                              | 20-30 per cent in 2050      | 30-60 per cent <sup>b</sup> in 2050                 |
| <b>Increase energy efficiency (Section 22.3.2)</b>             | Reduction in energy intensity over time (measured in terms of primary energy and GDP) | 1-2.5 per cent (2010-2050)  | 2.2-3.5 per cent (2010-2050)                        |

N: nitrogen.

<sup>a</sup> Not for all topics, the pathways found in the literature and discussed in this chapter were able to meet the selected target as presented in Chapter 20 (see Section 22.3.1 to 22.3.5).

<sup>b</sup> Renewable energy includes the full range of renewables and non-CO<sub>2</sub> emission reductions in the mitigation scenarios derived from the SSP scenarios (see Section 3.2.2).

2015; Le Blanc 2015). Understanding the interlinkages, beyond the clusters focused on here, is crucial for synergistic implementation and policy coherence (Nilsson, Griggs and Visbeck 2016; TWI2050 2018). Accounting for interlinkages can help enhance the effectiveness of implementation and, to some extent, also reduce the total burden and cost of achieving targets individually (Elder, Bengtsson and Akenji 2016). Furthermore, it can help with identifying coherent clusters of targets to be pursued together (Weitz *et al.* 2018).

Analysing the integrated nature of the SDGs has been a research area since their agreement in 2015. However, only a few broad studies so far have analysed interrelations across all SDGs (e.g. Prahdan *et al.* 2017; Zhou and Moinuddin 2017). Difficulties with such studies are that they generally do not look at specific measures, do not take into account future developments, and can only conclude correlations between targets, not causality. Studies that do take these elements into account in their analysis generally focus on a subset of SDGs (International Council for Science 2017; van Vuuren *et al.* 2015) or specific themes, such as energy (McCollum *et al.* 2018; Nerini *et al.* 2018), climate mitigation (von Stechow *et al.* 2016), air pollution (Elder and Zusman 2016), land use and food security (Obersteiner *et al.* 2016; Conijn *et al.* 2018), oceans (Singh *et al.* 2017) and ecosystem services (Wood *et al.* 2018).

These studies are either based on the existing literature – as is also the case in this chapter – or on dedicated modelling.

Overall, these studies identify more synergies than trade-offs within and among the SDGs and their targets. However, many interrelations are highly context-specific (Nilsson, Griggs and Visbeck 2016; Weitz *et al.* 2018). There are multiple links between two targets, with potentially different and sometimes conflicting interrelations. Furthermore, outcomes depend on the governance and geographical context, as well as the time-horizon taken (Nilsson *et al.* 2018), to name a few. Providing a full analysis of all interrelations across the measures and targets discussed in this chapter thus requires a dedicated, place-based analysis, which is beyond the scope of GEO-6. In this section, we therefore further elaborate on some of the interrelations among measures and targets between the different clusters for which the scenario literature concludes significant interrelations.

**Table 22.2** provides a broad overview of measures with strong synergistic effects and measures with strong trade-offs across the targets, based on the scenario assessments of Section 22.3.1 to 22.3.5 and a quick-scan presented in **Box 22.5**. From this set, key measures with respect to strong synergies and trade-offs are selected for a more in-depth discussion.

**Table 22.2: Measures with significant synergies or trade-offs across the selected targets**

|                | <b>Synergies</b>                                                                                                                                                                                                                                       | <b>Trade-offs</b>                                                                                                                                                            |

#### **Box 22.5: A snapshot of interrelations between the selected measures and targets**

To get an overview of the many interrelations across the selected measures and targets discussed in this chapter, an expert assessment has been conducted under the authors of this chapter. This expert assessment was compared with the literature and the input from authors of Part A of GEO-6. Experts were asked to score the interrelations using the seven-point scale of Nilsson, Griggs and Visbeck (2016). Interrelations were scored from the most positive score (the measure is indivisible to achieve the target) to the most negative score (the measure can cancel achievement of the target). The result (average score over the different expert scores) is presented in **Figure 22.9**.

Some clear patterns emerge from the analysis. Most interlinkages are flagged between the different measures and the targets that address climate change and biodiversity loss. Furthermore, in line with conclusions from earlier interrelation studies, there are more synergies than trade-offs. The strongest synergies are between measures and targets within the same cluster (see the synergies and trade-offs discussion for each of the individual clusters in Section 22.3). Finally, clear trade-offs are identified between the measures for yield improvement, bioenergy use and desalination, and a broad range of targets. However, as the strongest negative score was not given, the experts suggest that these trade-offs could be addressed with extra mitigating measures.

The analysis also concludes that the extent of the interrelations is not always straightforward. For many interrelations, the experts showed some level of disagreement. These stem partly from different assumptions on the overall context in which the measures are taken, but also that several measures can have both synergies and trade-offs requiring some kind of assessment of their strength. From a similar exercise in the literature, focusing on SDGs on health, energy and oceans, it was concluded that interactions depend on key factors such as geographical context, resource endowments, time-horizon and governance (Nilsson *et al.* 2018). **Figure 22.9** thus only presents a first snapshot or quick-scan of key interrelations involved. To draw policy conclusions, a more dedicated analysis is required. This includes systematic reviews, coding existing literature with respect to specific interactions and integrated assessment modelling, with the latter analysing interlinkages within and across a broader range of subsystems than is currently done (see also Nilsson *et al.* 2018).

Figure 22.9: Quick-scan of synergies and trade-offs between selected measures and targets

| Cluster                                  | Measure                                                   | SDG 1.1: Eradicate extreme poverty | SDG 2.1: End hunger | SDG 3.2: End preventable death of children under 5 | SDG 6.1 and 6.2: Achieve universal access to safe water and sanitation | SDG 6.3: Improve water quality | SDG 6.4: Reduce water scarcity | SDG 7.1: Achieve universal access to modern energy services | SDG 11.6: Improve air quality in cities | SDG 13: Limit climate change | SDG 14.1: Reduce marine nutrient pollution | SDG 14.3: Minimize ocean acidification | SDG 14.4: Sustainably manage ocean resources | SDG 15.3: Achieve land degradation neutrality | SDG 15.5: Halt biodiversity loss |

## **Selected measures with significant synergies across the selected targets**

### **Education**

Education is a basic human right (Universal Declaration of Human Rights, Article 26), an SDG in itself (SDG 4) and, like health, a measure of human development (United Nations Development Programme [UNDP] 2016). Improved education has considerable synergistic effects with both well-being and environment-related targets (United Nations Educational, Scientific and Cultural Organization [UNESCO] 2017). Education, especially for women, has a particularly strong connection with health outcomes. It can significantly affect child health, through reduced malnutrition (Smith and Haddad 2000; Marmot, Allen and Goldblatt 2010) and improved hygiene. Over half the decline in child mortality from 1970 to 2009 can be attributed to increased education in women of reproductive age (Gakidou *et al.* 2010). In addition, higher levels of education are associated with lower fertility rates, increased economic growth, reduced poverty levels and more democracy (Dickson, Hughes and Irfan 2010; Lutz and Samir 2013; Dickson, Irfan and Hughes 2016). The link between improved educational metrics and economic growth and poverty alleviation are well established (Hulme and Shepherd 2003; Verner 2004; Awan *et al.* 2011; Cremin and Nakabugo 2012; UNDP 2016). Improved education also contributes to coping with climate change and coping with the increased occurrence and severity of natural disasters (Cordero, Todd and Abellera 2008; Kagawa and Selby 2012; Chang 2015). Climate change education contributes to capacity-building for decision makers, but also empowers people to implement their own adaptation strategies, among other things, by equipping people to understand complexity and perceive risks (Mochizuki and Bryan 2015). Improving access to safe drinking water, sanitation and hygiene, and sound management of freshwater ecosystems can also benefit from education (Çoban *et al.* 2011; Michelsen and Rieckmann 2015; Karthe *et al.* 2016).

### **Dietary change**

Dietary change, particularly towards reduced ruminant consumption, is synergistic with achieving multiple environmental targets. Furthermore, it can help end hunger and improve human health, with minimal effect on land degradation and biodiversity. In particular, dietary change can reduce cropland expansion (Stehfest *et al.* 2009; Tilman and Clark 2014) and at the same time increase food supply (Foley *et al.* 2011). In addition, dietary change can result in reduced greenhouse gas emissions, reduced pollution, reduced water use and improved health. Dietary change results in reduced emissions of methane from reduced livestock consumption, N<sub>2</sub>O and ammonia from reduced fertilizer application, and CO<sub>2</sub> from reduced cropland conversion (Stehfest *et al.* 2009; van Vuuren *et al.* 2017a). The decrease in greenhouse gas emissions associated with dietary change can be significant, with greenhouse gas emission reductions of as much as 70–80 per cent possible (Aleksandrowicz *et al.* 2016). Reducing methane emissions also has positive implications for air quality, as it is a precursor to ozone pollution. Reduction in nitrogen fertilizer use associated with changes in diet has the co-benefit of improving air quality and health by reducing emissions of ammonia and the subsequent formation of fine particulate matter (Zhao *et al.* 2017; Giannadaki *et al.* 2018). Reductions in nitrogen fertilizer use associated with changes in diet also have positive implications for water quality. Reduction in water use can be as much as 50 per cent (Aleksandrowicz

*et al.* 2016; Jalava *et al.* 2016; Bijl *et al.* 2017; van Vuuren *et al.* 2017a). Finally, dietary shifts to lower consumption of livestock products yields benefits in all-cause mortality (Milner *et al.* 2015; Aleksandrowicz *et al.* 2016; Springmann *et al.* 2018). It should be noted that some researchers do not find a significant increase of food availability and access for poor communities, resulting from reduced meat consumption in high-income countries (Moyer and Bohl 2018). To be effective, measures to shift diets need to take into account the regional and developmental context (World Economic Forum 2017).

### **Air pollution control**

Reduced air pollution has clear positive impacts on human health. However, there are also synergies with agricultural production, biodiversity and climate change. Ozone is a strong oxidant that can enter plants through the leaves and damage vegetation by affecting photosynthesis and other physiological functions. Several studies have reviewed the links between ozone concentrations, forest productivity and agricultural yields (e.g. Ainsworth *et al.* 2012; Talhelm *et al.* 2014). Averaged over 2010–2012, ozone is estimated to have reduced wheat yield by 9.9 per cent in the Northern Hemisphere and by 6.2 per cent in the Southern Hemisphere (Mills *et al.* 2018). Shindell *et al.* (2012) quantified how measures to reduce black carbon and methane lead to reduced ozone and thus improved agricultural yield, production and value. They found an increase in production of approximately 27 million tons and 24 million tons due to measures to reduce methane and black carbon, respectively. Avnery, Mauzerall and Fiore (2013) report that methane emission controls could increase production of wheat, maize and soybean in North America in 2030 by up to 3.7 million tons. Capps *et al.* (2016) showed that reduction in emissions of nitrogen oxides (NO<sub>x</sub>) as a co-benefit of limiting CO<sub>2</sub> emissions from coal power plants in the United States of America could reduce potential productivity loss due to ozone exposure by as much as 16 per cent and 13 per cent for individual crops and tree species, respectively. Reduction in SO<sub>2</sub> and NO<sub>x</sub> emissions leads to reductions in acid and nitrogen deposition, and subsequent ecosystem impacts such as eutrophication (Greaver *et al.* 2012).

## **Selected measures with significant trade-offs across the selected targets**

### **Land-based mitigation**

Nearly all climate scenarios consistent with the Paris Agreement rely on significant use of land-use based mitigation (see also **Box 22.2**). This includes the use of bioenergy, avoiding deforestation and afforestation/reforestation. A special case is the role of negative emissions (bioenergy plus carbon-capture-and-storage and afforestation), which seems a requirement for the stringent climate targets – certainly those which allow for higher short-term emissions (Fuss *et al.* 2014; van Vuuren *et al.* 2017a). The use of land-based mitigation options can have important implications for other sustainability targets, in particular food security and protecting terrestrial biodiversity (Wicke 2011; Reilly *et al.* 2012; Calvin *et al.* 2014; Popp *et al.* 2014; Smith *et al.* 2016; Heck *et al.* 2018). For example, pathways with high bioenergy use can negatively impact land degradation and biodiversity, as these pathways would typically lead to higher food prices, reduced forest cover and reduced natural lands. While pathways with significant afforestation could potentially lead to a synergy with reducing biodiversity loss they could still lead to increased competition for land and thus potentially to higher food prices. Bioenergy

use could also lead to higher demand for water and more fertilizer use, with the latter increasing the risk of eutrophication from higher nitrogen and phosphorus run-off (e.g. Gerben-Leenes, Hoekstra and van der Meer 2009; Hejazi *et al.* 2015; Mouratiadou *et al.* 2016).

Although bioenergy is one of several important options for future energy systems, increasing global trade and consumption of bioenergy has been accompanied by a growing concern about the environmental, ecological and social impacts of modern bioenergy production (Wicke 2011). For example, trade-offs between bioenergy and food security, and between the impact of biomass on poverty reduction and on the environment have been widely reported (Wicke 2011; Smith *et al.* 2016). Yamagata *et al.* (2018) report water-food-ecosystem trade-offs for global negative CO<sub>2</sub> emission scenarios. They point to three outstanding conflicts:

- ❖ vast conversion of food cropland into rain-fed bio-crop cultivations yields a considerable loss of food production;
- ❖ when irrigation is applied to bio-crop production, the bioenergy crop productivity is enhanced – this reduces the area necessary for bio-crop production by half, but water

consumption is doubled, increasing water scarcity and groundwater depletion; and

- ❖ if conversion of forest land for bioenergy crop cultivation is allowed, large areas of tropical forest could be used for bioenergy crop production, which can cause serious extensive decline in carbon stock and related ecosystem services, leading to increasing CO<sub>2</sub> emissions from land-use change.

More attention needs to be paid to the co-benefit of biodiversity conservation and climatic change mitigation activities for optimizing various sustainability benefits.

**Figure 22.10** illustrates that in the majority of the scenarios the use of bioenergy increases for more stringent climate targets. In the SSP scenario database in fact all scenarios consistent with the targets of the Paris Agreement lead to a demand for bioenergy of more than 200 exajoules/year in 2050. Earlier, the Intergovernmental Panel on Climate Change (IPCC) did an assessment of the bioenergy supply in 2050 under different sustainability constraints. It concluded that at least 100 exajoules/year would be available under these constraints. It also concluded that possibly 300 exajoules/year

**Figure 22.10: Global mean temperature increase in 2100 versus bioenergy use in various SSP reference scenarios and derived mitigation scenarios**

The different background colors indicate the Paris Climate Targets (vertical lines, starting at 1.5° and 2°C) and the range for sustainable biodiversity supply indicated by the Intergovernmental Panel on Climate Change (IPCC) (IPCC indicated 100 exajoules/year was most likely available; 300 exajoules/year could be available).

Source: Riahi *et al.*, 2017; Vuuren *et al.* (2018).

would be available (but with a much higher level of uncertainty). A bioenergy potential of about 100 exajoules/year was found to have high agreement of being sustainable, while values above that threshold had lower levels of agreement as to the sustainability of the bioenergy supply (Creutzig *et al.* 2015). This means that no scenarios in the database would actually be consistent with a stringent interpretation of both the Paris target and the sustainability constraints on bioenergy. Van Vuuren *et al.* (2018) explored different alternative pathways to reach ambitious climate targets that could possibly reduce the need for negative emissions (and thus bioenergy). These scenarios, for instance, assumed diet change towards low-meat diets consistent with health recommendations, ambitious implementation of non-CO<sub>2</sub> emission reduction or alternatively the production of cultivated meat. Such assumptions could lead to a much lower demand for negative emission technologies and thereby bioenergy in combination with carbon-capture-and-storage. Recently, a model comparison study looked into stringent climate policy scenarios with limited bioenergy supply (Bauer *et al.* 2018). Here, some models did find low-bioenergy pathways through careful optimization of their use (e.g. the application of bioenergy in combination with carbon-capture-and-storage only for production of transport fuels).

#### Agricultural intensification

Improving agricultural yields is seen as a prerequisite for producing enough food and bioenergy to meet future demand while at the same time minimizing or completely eliminating the need for agricultural land expansion. The use of fertilizers can potentially deliver yield increases but can also have severe consequences for freshwater and ocean quality and related ecosystems, as well as climate change (Bouwman *et al.* 2017). Impacts on biodiversity largely depend on how higher yields are achieved.

Improving yields can increase overall food availability, especially when these yield improvements are achieved in current low-yield countries and areas with high prevalence of undernourishment. At the same time, it can negatively impact nutrition if high-yield crops contain less micronutrients than average dietary requirements (DeFries *et al.* 2015; Rao *et al.* 2018). Furthermore, when yields are increased without specifically addressing distributional aspects, the increased production does not necessarily reach the communities most in need. At the same time, obesity in high- and middle-income countries could rise as a result of overall decreasing food prices (van Vuuren *et al.* 2015). Finally, when yield increases are accompanied by scale increase, smallholders might be forced to move to cities, which does not necessarily improve their income situation.

Improving agricultural yields reduces land demand for growing crops, reducing pressure on existing natural lands, thus potentially reducing deforestation and biodiversity loss. On the other hand, increasing yields usually demands higher levels of fertilizers, pesticides, and water for irrigation, thus negatively impacting water quality and water scarcity. Use of nitrogen fertilizers also causes higher N<sub>2</sub>O emissions, meaning trade-offs with climate change mitigation. Mechanization and monocultures associated with yield increases in the past led to erosion, soil compaction and loss of soil organic

carbon, increasing the likelihood of land degradation. This can be further exacerbated by leaching and salinization of land from long-term irrigation. All these factors negatively impact biodiversity.

#### Poverty alleviation and environmental protection

Higher incomes, decreasing hunger and improved access to water and energy are expected to push up demand for food, water and energy, thereby increasing environmental pressures. In reality, however, both synergies and trade-offs exist – and, while some are important to take into account, others are relatively small. Scenario analysis shows that eradicating hunger and providing universal access to modern energy services (beyond production increases that result from population and economic growth) would not necessarily negatively affect global biodiversity or climate change (e.g. Riahi *et al.* 2012; van Vuuren *et al.* 2015; Dagnachew *et al.* 2018). Although most studies addressing access to modern energy services show that a decrease in biomass use is generally accompanied by an increase in the use of fossil-fuel-based products (e.g. liquified petroleum gas, natural gas, electricity), the increase in global CO<sub>2</sub> emissions is usually small (Dagnachew *et al.* 2018). Furthermore, increasing CO<sub>2</sub> emissions are partly compensated by reduced emissions from deforestation and black carbon. Similarly, the additional demand for food, resulting from the eradication of hunger, is estimated to be relatively small, especially when compared to current production levels and the required increase to keep pace with an increasing and more wealthy global population (van Vuuren *et al.* 2015). If hunger eradication would be facilitated by a redistribution of current consumption levels, the required increase in production would be even less (van Vuuren *et al.* 2015). Obviously, however, further development beyond the minimum levels could be associated with further environmental pressure. Therefore, it is important to add sustainability considerations in policies that aim for higher levels of economic development in order to prevent such a trade-off.

Several studies have emphasized another potential trade-off between achieving environmental targets and ensuring access to basic resources and services. This is because, in many cases, policies for achieving environmental targets could lead to a cost increase. While such cost increases might be relatively unimportant for populations with high income levels, they could have a strong impact on the poor. It has been shown that if implemented without additional compensatory measures, climate policy could lead to negative impacts on access to electricity (Dagnachew *et al.* 2017), access to clean fuels for cooking (Cameron *et al.* 2016) and on food security (Hasegawa *et al.* 2018).

## 22.5 Conclusions and recommendations

We have assessed the scenario literature to analyse a broad range of measures relevant for achieving the selected environmental targets of the SDGs and related MEAs, with a specific focus on synergies and trade-offs. Overall, the scenario literature provides a broad range of options to move towards achieving these targets, but this knowledge is hampered by the lack of concrete pathways.

### 22.5.1 Knowledge gaps

The discussion in this chapter shows that model-based scenario analysis can be an effective tool to support integration of knowledge in the effort required to reach the environmental targets of the SDGs and related MEAs and to highlight the linkages across time, scales and issues.

However, from the literature assessment, it can be concluded that the scenario literature is still patchy on analysis to show possible pathways to achieving the SDGs. No fully integrated scenario studies exist. Furthermore, the literature is well advanced in some areas, while for other areas literature is mostly lacking. As a result, it is still difficult to estimate the exact size of different strengths and weaknesses of specific measures. There is extensive literature that discusses pathways to achieve the selected targets in the energy, air and climate cluster and, although to a lesser extent, also in the agriculture, food, land and biodiversity cluster. In the latter case, these studies mostly address hunger and biodiversity, with relatively few scenario studies that aim to meet specific targets and virtually no scenario studies that address how to achieve land degradation neutrality. Ocean acidification is well discussed in the literature, mostly linked to scenarios that address climate targets.

For the freshwater, oceans and human well-being (health) clusters, target-seeking scenarios are much less common in the literature. For the freshwater cluster, scenarios look at water scarcity issues, while the literature around WASH and water quality are sparse. For health (e.g. child mortality), very few target-seeking scenarios were found in the literature. Finally, as already concluded in Chapter 21, quantitative scenario studies on chemicals and waste and wastewater are almost non-existent.

While many synergies and trade-offs are discussed in the literature, besides thematic studies (mostly based on existing scenario literature), a thorough overview of all relevant interrelations across the measures and targets discussed in this chapter is still lacking. This is partly because there are still caveats in the scenario literature and because these interrelations are highly context-specific, making it difficult to provide unambiguous scores. Sectoral studies looking at interlinkages often emphasize the key role of that sector in achieving the overall targets, providing very few options for prioritization. As result, large gaps exist in current understanding of linkages with other sectors or themes.

It should be noted that indirect interlinkages often also exist and that, in many cases, interlinkages can lead to both synergies and trade-offs. For example, fertilizer application could lead to higher yields, requiring less land and thus reducing biodiversity loss and potentially land expansion, while it would also increase nitrogen and phosphorus run-off leading to freshwater and marine nutrient pollution, causing hypoxia and harmful algal blooms, and related biodiversity loss. These complex interrelations and the absence of broad interlinkage studies imply that more dedicated analyses are

required, including systematic reviews of the existing literature and dedicated integrated assessment modelling, with specific attention to interlinkages that are currently underexplored.

### 22.5.2 Policy recommendations

From the scenario analysis, it can be concluded that pathways exist towards achieving a broad range of environmental targets of the SDGs and related MEAs, but they require a clear break with current trends (transformational change). Marginal improvements will not suffice. Large, transformative changes are needed to realize the different targets. Significant improvements in resource efficiency with respect to land, water and energy are required, including an almost 50 per cent increase in agricultural yields compared with current trends, and a doubling of energy efficiency improvement.

Achieving the targets will require a broad portfolio of measures, including a mix of technological improvements, lifestyle changes and localized solutions. The many different challenges require dedicated measures that improve access to, for example, food, water and energy, while at the same time reducing the pressure on environmental resources and ecosystems. A key contribution may come from a redistribution of access to resources. From a production perspective, the changes would include elements such as cleaner production processes and decoupling of resource consumption from economic development. Also changes in demand-side efficiency and consumer behaviour should be considered. The latter may include dietary changes towards reduced ruminant consumption, but also changes in transport moving towards less energy-intensive transport modes.

Understanding interlinkages between measures and targets is crucial for synergistic implementation and policy coherence. Where measures generally aim at achieving specific targets, or a cluster of targets, the analysis showed some clear synergies between measures and targets in other areas. Examples include education, dietary change and air pollution control, with all three having positive impacts on both a Healthy Planet and Healthy People. This chapter also highlights important possible trade-offs, such as the impact of climate policy on the costs of energy and consequently energy access. In many cases, it is also possible to address these trade-offs by introducing mitigation measures (in the example above, specific policies to support energy access for the poor could prevent specific trade-offs).

The economic and technical potential is available to move towards implementation of the targets in Chapter 20. However, a full consideration also needs to account for social feasibility. The feasibility of the transformation processes can only be discussed in the light of current trends and ongoing innovation processes of citizens and businesses worldwide. Chapter 23 will do this. Finally, in Chapter 24, we will discuss how policy measures could induce the transformations presented here. In many cases, social feasibility can be enhanced by ensuring a proper consideration of possible synergies and trade-offs.

# Chapter 23

## Bottom-up Initiatives and Participatory Approaches for Outlooks

**Coordinating Lead Author:** Laura Pereira (Centre for Complex Systems in Transition, Stellenbosch University)

**Lead Authors:** Ghassem Asrar (Pacific Northwest National Laboratory), Laur Hesse Fisher (Massachusetts Institute of Technology), Angel Hsu (Yale University), Jeanne Nel (Vrije Universiteit Amsterdam), Nadia Sitas (Council for Scientific and Industrial Research, South Africa), James Ward (University of South Australia), Joost Vervoort (Utrecht University),

**Contributing Authors:** Odirilwe Selomane (Stockholm Resilience Centre, Stockholm University), Christopher Trisos (National Socio-Environmental Synthesis Center, United States of America), Thomas Malone (Massachusetts Institute of Technology), Yaolin Zhang (Yale-Nus College)

**GEO Fellows:** Rohan Bhargava (Utrecht University), Mandy Angèl van den Ende (Utrecht University), Amy Weinfurter (Yale University)

# Executive summary

**The challenge of sustainable development offers the opportunity for more effective integration of global and local scenario approaches in environmental assessments and outlooks to support decision-making for all 17 Sustainable Development Goals (SDGs) at all levels (i.e. local, national, regional and global) (established, but incomplete).** A bottom-up perspective on the future, which is based on local scenarios and practices offers potential benefits for exploring alternative futures that are grounded in local realities and start with existing practical action that can be appropriately scaled. Linking top-down and bottom-up approaches to multilevel scenario development provides an opportunity for global processes to inform local actions and for taking account of local actions in global agreements. Co-developing approaches with diverse stakeholders will help to overcome the current limitations in scaling innovations up, out and deep, and in transferring valuable lessons and results from local to both regional and global levels, and vice versa {23.1}.

**The bottom-up approach engages a broad range of scientific and action-oriented knowledge, perspectives and opinions about a desirable world in the future and the ways to get there, including pathways to achieve long-term sustainability goals (e.g. the SDGs) (established, but incomplete).** Since there is no single answer to achieving sustainability, having multiple perspectives is essential for defining different desirable futures. Through a combination of crowdsourcing platforms, participatory workshops in different regions of the world, analyses of existing sustainability solutions and an assessment of regional outlooks, novel methods for linking the generic results of global models with complementary information and insight from the local level can be undertaken. The outcome from the implementation of such an innovative framework provides useful and relevant information and knowledge for policymakers and practitioners to make more informed decisions about how to achieve a sustainable future {23.4, 23.6}.

**A groundswell of bottom-up efforts to realize the SDGs and other multilateral environmental agreements is currently under way, as are efforts to support and facilitate collaboration among them (established, but incomplete).** Reviewing platforms of bottom-up initiatives provides a preliminary understanding of the breadth and depth of ideas, actions and programmes that seek to help achieve sustainable development objectives. The clear majority of the platforms have a global level of coverage, drawing on examples and encouraging connections from all over the world. Most of the platforms facilitate knowledge-sharing and the identification of solutions in two ways. First, this is through the collection of examples, solutions and best practices (e.g. United Nations Framework Convention on Climate Change [UNFCCC] Momentum for Change Lighthouse Initiative, PANORAMA Solutions for a Healthy Planet; WOCAT; see Annex 23-1), and, second, by creating forums for sharing technical or regional tools and know-how for on-the-ground activities (e.g. Biofin Knowledge Platform, ClimateTechWiki). Other platforms use contests or crowdsourcing to generate and synthesize solutions to challenging questions (e.g. VertMTL, MIT Climate CoLab). These platforms highlight the importance of involving a wider variety of people to complement government policies and initiatives {23.9}.

**The GEO Regional Assessments highlight important global environmental pressures in the future, but also emphasize regional priorities and solutions that are critical in decision-making processes (well established).** GEO-Africa focused on so-called leapfrogging development and emphasized low-carbon, resilient infrastructure for meeting food, energy, water and housing needs while maintaining the continent's ecological assets. Asia and the Pacific had different regional priorities, including disaster-risk reduction as an important consideration, and smart cities were outlined as potential solutions, given population and urbanization trends. Latin America and the Caribbean focused on decoupling economic growth from the use of natural resources through sustainable management and ecosystem-based resilience. Europe recognized the need for lifestyle and consumption changes to reach sustainability goals. North America did provide a scenario analysis but emphasized technological innovation and the data revolution as mechanisms for achieving sustainable development. West Asia emphasized peace and security and the importance of integrated resource management to manage limited natural resources such as water. While climate change is a driver considered across all the regions, adaptation and mitigation pathways are suggested within framings {23.10}.

**Data and knowledge gaps exist in the bottom-up analysis, emphasizing a need to broaden out the participatory approaches across scales (unresolved).** The gaps associated with these bottom-up processes can be grouped into four broad categories as follows. (1) Gaps to do with interconnections across regions: connections and interdependencies across regions were not highlighted in most Regional Assessments. (2) Gaps to do with cross cutting themes such as gender, equity and inequality are absent in all but the assessments for Africa and Latin America and the Caribbean. These are more likely to be addressed through a bottom-up approach. (3) Gaps to do with specific resources: interventions for freshwater and oceans are the least addressed in bottom-up initiatives. The Climate CoLab proposals and initiatives focused on freshwater interventions mostly on WASH (water, sanitation and hygiene) and no bottom-up initiatives addressed desalination or ocean regulation. (4) Gaps to do with human well-being: these include solutions predominantly focused on poverty alleviation, while child and maternal health care was addressed by only one Climate CoLab proposal. This highlights an important area for government interventions to target these specific areas {23.9}.

**Participatory approaches to identify and assess transformative solutions and envision pathways towards greater sustainability can provide decision makers with a useful landscape of initiatives and concrete synergistic solutions (established, but incomplete).** By engaging with stakeholders through global workshops and Climate CoLab, GEO-6 could collect many diverse solutions and visions that can complement, and potentially be fed into, quantitative information in integrated assessment models. These participatory approaches can help to shift the focus of outlooks work from the 'what' to the 'how'. For example, there was a strong emphasis on food systems as critical intervention points to move towards a healthy planet, healthy people. Chapter 22 identifies yield-improvement targets and general

solutions such as diet change and reduced pesticide use. These are complemented by initiatives from the workshops and the Climate CoLab that elaborate on specific campaigns taking place right now that provide examples of how to promote diet change and innovations for more high-yield sustainable farming, e.g. Apps to promote sharing economies to reduce food waste in cities; urban agriculture; aquaculture; indigenous and local knowledge exchanges {23.12}.

**Transformations to sustainability require both social and technical innovations as well as an enabling policy environment in which to scale these ideas and solutions appropriately** (*established, but incomplete*). Sustainability transformations refer to the systemic changes that are needed to move from a business-as-usual trajectory to a more sustainable future. Transformation is often broken down into multiple phases with temporal periods related to a problematic status quo, a preparation phase in which innovations begin to develop, a navigation/acceleration phase in which innovations grow and become part of the new system, and an institutionalization phase in which a more desirable system is made sustainable in the longer term. Each of these phases requires strongly enabling governance conditions for transformations to occur successfully. These enabling conditions can best be broken into:

- ❖ Supporting conditions for the appropriate scaling of innovations (establishing and supporting markets for innovations; supporting innovation experimentation and learning; financial resource mobilization; human resource mobilization)

- ❖ Disrupting conditions for the weakening of existing, problematic structures (control policies; rules reform; reduction in existing regime support; changes in networks and key actors and their relationships) {23.12}.

**The combined analysis of bottom-up and regional solutions for achieving a healthy planet, healthy people highlight the need to consider a full range of actors, to enable distributive justice and to ensure fair perceptions about where action should be expected to take place** (*established, but incomplete*). Many solutions offer the opportunity for developing countries to leapfrog onto more sustainable and equitable development trajectories. The use of information and communications technology (ICT) plays a major role as a tool for driving change. Furthermore, the roles of different societal actors are made explicit in bottom-up pathways. For instance, there is an important role for city-level government actors, in many of the initiatives assessed in this report, as well as for global networks, like sustainable cities or energy cooperatives. Based on the experiences of GEO-6, participatory work in the future can be enhanced by engaging globally with stakeholders from a greater diversity of backgrounds, focusing on policy-relevant data collection, such as actor roles and barriers to change, and further refining processes of transformation and the equity implications of proposed interventions {23.13}.

## 23.1 Introduction

The rapid pace and scale of societal and environmental changes in the Anthropocene, where human activity dominates most of the Earth's processes (Crutzen 2006; Leach *et al.* 2013; Steffen *et al.* 2015) are changing how assessments are carried out. Global environmental assessments (including GEO-6) are moving the focus from current trends (e.g. what is the current state of biodiversity?) towards the required transformations for a more sustainable future, and the means to get there (e.g. what interventions are needed to keep global warming below 1.5°C?) (Kowarsch *et al.* 2017; Minx *et al.* 2017). Decision-makers, scholars and practitioners are demanding a deeper and more explicit focus on response options and policy analysis (Jabbour and Flachslund 2017). This shift in intention and direction is especially relevant in the context of the Sustainable Development Goals (SDGs), where nations have set the ambition to achieve a broad range of globally accepted and integrated social, economic and environmental targets for 2030. However, medium- to long-term decision-making is complicated by the fact that the future is uncertain, and it is often not obvious how existing policies and practices can be transformed to achieve desired future outcomes (Miller 2013; Miller, Poli and Rossel 2013; Bennett *et al.* 2016).

Global environmental assessments distil, synthesize and interpret existing information in ways that are relevant to decision makers and can help governments to achieve consensus when negotiating complex international accords and agreements (e.g. the Paris Climate Agreement and the United Nations 2030 Agenda for Sustainable Development) (Jabbour and Flachslund 2017). However, while global environmental assessments often rely on global-scale quantitative scenarios to assess potential futures and to navigate uncertainty (van Vuuren *et al.* 2012), they struggle to integrate dynamics that can bridge local, regional and global scales (Bennett *et al.* 2003). Furthermore, integrated assessment models like those employed in Chapter 22 to develop quantitative global scenarios, struggle to simulate decisions that engage multiple jurisdictional levels, as well as diverse actors, and therefore cannot capture the impact of trends emerging from subglobal scales. As a result, while such scenarios present archetypal, globally unified futures, it is not always clear to decision makers how national policies can use these in ways that are geared for local decisions and action (Biggs *et al.* 2015; Pereira *et al.* 2018a).

The successful implementation of transformative pathways requires an understanding of:

- i. how transformational changes occur at local, national, regional and global levels;
- ii. which actors and what disruptive technologies (i.e. those that replace incumbent technologies creating new markets) drive such changes; and
- iii. what the consequences of transformative action might be in terms of cross-scale connections (Cash *et al.* 2006; Feola 2015; Patterson *et al.* 2017).

This is where the combination of top-down scenarios and bottom-up analyses is crucial.

This chapter assesses participatory processes and local practices seeking transformed futures and grounds the interventions proposed in Chapter 22 with existing examples. The following sections provide background information on cross-level interactions in sub-global assessments and existing research on aggregating local practices towards effective implementation of the SDGs. The later sections describe the methodology used for the GEO-6 bottom-up analysis, followed by the assessment findings and insights gained from the analysis.

## 23.2 Integrating global assessments and bottom-up analyses

The assessment of transformation pathways can be conducted from global to local, or from local to global levels. For example, Chapters 21 and 22 present global scenario and pathway analyses, but such analyses can also be conducted at local and regional levels. Additionally, pathways can be formulated from the bottom-up by using existing, potentially transformative initiatives as a starting point (Pereira *et al.* 2018b). As described in Chapter 22, global scenarios integrate models and data at the global scale to project plausible future pathways and outcomes. These methods are used to explore a wide range of possible futures (explorative scenarios), and the impacts of recommended solutions or policy options (target-seeking scenarios) (van Vuuren *et al.* 2012; Intergovernmental Science-Policy Platform on Biodiversity and Ecosystem Services [IPBES] 2016). Most global approaches and integrated assessment models cannot, however, engage effectively with: (1) the roles and behaviour of specific actors and the multilevel political mechanisms that support transformation, (2) disruptive technologies and, (3) geographic disaggregation.

Participatory, local scenario approaches can, in contrast, use existing narratives and initiatives to imagine and observe actor behaviour, consider disruptive change and develop future pathways that are locally contextualized and practical (Merrie *et al.* 2018). However, these local scenarios face the challenge of scaling up and transferring the accumulated knowledge and results from individual cases, from local to regional and global levels. Further, local approaches lack the specificity of model-based approaches since they are often only partially quantified or aggregated, limiting their applicability at higher levels.

From these alternative starting points, multilevel scenarios can be developed in two directions. Global scenarios can be downscaled in a top-down manner for use at regional and local levels; and local scenarios can be aggregated through bottom-up approaches to complement global scenarios by inserting local contexts to address biases and assumptions. The downscaling of global scenarios has been investigated and published widely (Zurek and Henrichs 2007; Mason-D'Croz *et al.* 2016; Palazzo *et al.* 2017). The creation of global scenarios through the aggregation of bottom-up approaches or through other innovative scaling up of local scenarios has, by contrast, received little research attention. This area offers many potential benefits for integrating more imaginative futures across scales in global environmental assessments to provide more useful information for informing policies and decisions (Bennett *et al.* 2016).

## 23.3 Sub-global assessments in a multilevel context

Regional or sub-global assessments based on top-down scenarios offer useful insights and experience on navigating multi- and cross-scale dynamics. There are significant challenges associated with the creation and connection of scenarios across different scales and levels, but also significant opportunities for greater policy relevance. The existing literature has mostly assumed that higher-level (global) scenarios can serve as a framework for lower-level (regional, national or local) scenarios in five ways (Zurek and Henrichs 2007; Table 1. p.1292):

- i. scenarios between different levels are viewed as being *equivalent* in all aspects if what is considered true at the global level is also true at the local level;
- ii. they are *consistent* when all the key assumptions that frame global scenarios can be used to constrain local-level scenarios. This is generally how regional GEO assessments were developed prior to GEO-6 (i.e. the Regional Assessments discussed in this chapter);
- iii. less directly connected scenarios are considered *coherent* if they share some, but not all, basic assumptions about the future across all levels – with other assumptions typically being specific to each level. An example is a set of regional scenarios created with West African policy concerns in mind but connected in terms of some key assumptions to the global scenarios developed by the Intergovernmental Panel on Climate Change (IPCC) community (See Palazzo *et al.* 2017);

- iv. *comparable* scenario sets investigate the same scope of topics and issues, but are not connected in terms of key assumptions about the future. The regional IPBES assessments followed this process to a certain extent by using scenario archetypes as tools for comparison across the different regions (Sitas and Harmáčková *et al.* submitted for publication); and
- v. *independent* scenarios may extend this further, based on different concerns and focus.

The scientific literature demonstrates how higher-level scenarios can be integrated with more local scenario sets – with scenario links ranging from those that are close to equivalency (Kok *et al.* 2015) to those having comparable scenario sets (Mason-D'Croz *et al.* 2016). There is a major gap, however, in the existence of studies that use local- and regional-level scenarios to inform global-level scenarios through a bottom-up approach. This is a major new focus for the outlooks presented by GEO-6.

Both GEO and IPBES share an interest in bottom-up future scenarios (IPBES 2016; Rosa *et al.* 2017; Lundquist *et al.* 2017). IPBES regional assessments offer an important point of comparison that include a broad review of sub-global scenarios and pathways efforts – (see Box 23.1). Another highly relevant example of the use of regional pathways and scenarios is the CGIAR Research Program on Climate Change, Agriculture and Food Security (Vervoort *et al.* 2014). This enables understanding of how pathway development can be directly connected to policy formulation across different sub-global regions.

### Box 23.1: IPBES and bottom-up scenario processes

The IPBES methodological assessment on scenarios and models explored the basis for how scenarios can be employed as tools for decision-making (IPBES 2016). Like GEO, IPBES aims to link science with policy on a variety of scales through Regional Assessments, which are used as a scientific knowledge base for policy development. Generally, IPBES focuses on the planet's state related to biodiversity, ecosystems and nature's contributions to people, grounded in interactions between the human and non-human world (Pascual *et al.* 2017). Findings of the regional assessments show that ecosystems, and consequently their services, are increasingly degrading, thus there is high need for policies addressing this challenge to be investigated from the local to the global (IPBES 2016). IPBES is undertaking scenario reviews both at global levels (IPBES Global report in preparation) and regional levels (IPBES 2018a; IPBES 2018b; IPBES 2018c; IPBES 2018d), allowing for a more specific focus on how bottom-up futures can contribute to global narratives and assist with better understanding of how to achieve more desirable futures, coupled human-nature systems and sustainable development (Lundquist *et al.* 2017).

There is increasing consensus in the literature that scenarios could be made more useful, especially in the IPBES process, through the creative development of more stakeholder-engaged bottom-up, diverse, multi-scale scenarios that are consistent within a global scenario context (Kok *et al.* 2016; Rosa *et al.* 2017). This has been reinforced in the findings for a need to build capacity in the role of scenarios in decision-making – a key finding in some of the IPBES regional assessments (See IPBES 2018a; IPBES 2018b). In response to this, the IPBES 3c Expert Group on scenarios and modelling decided on a way forward to start filling in the gaps on scenario exercises (Rosa *et al.* 2017).

The expert group recognized that:

1. scenarios fail to incorporate policy objectives related to nature conservation and social-ecological feedbacks
2. scenarios are typically relevant at only a particular spatial level, and
3. nature and its contributions to people are treated as the consequence of human decisions rather than being at the centre of the analysis (Lundquist *et al.* 2017).

To address these issues, the expert group initiated the development of a set of multiscale scenarios for nature futures based on positive visions for human relationships with nature. The first step in this process was a visioning workshop with multi-sectoral stakeholders and experts (4-8 September 2017 in Auckland, New Zealand; see Lundquist *et al.* 2017). Using an adapted Manoa mash-up approach based on Pereira *et al.* (2018a), the workshop resulted in seven visions of positive nature futures based on a bottom-up scenario approach that will be further developed in the workplan of the expert group. The process of refining the visions into scenarios that can have a quantitative element for modelling, as well as for filling in gaps, will involve iterative cycles of visioning, stakeholder consultation and modelling through a variety of different forums (Lundquist *et al.* 2017).

### 23.4 Bottom-up futures based on existing local practices

The need to consider the contributions of bottom-up initiatives is being recognized formally in global assessments. This demonstrates both political commitment to bottom-up implementation and the potential offered to achieve environmental goals, such as decarbonization by 2050. In the Fifth Assessment Report of the IPCC, Chapter 12 on human settlements, infrastructure and spatial planning acknowledged the role of local actors in global climate mitigation (Seto *et al.* 2014). The United Nations Environment Programme synthesis report of the Emissions Gap Report 2016 included, for the first time, an assessment of multiple studies that quantified the additional contribution of local actors to mitigation (United Nations Environment Programme [UNEP] 2016). This analysis found that subnational and non-state actors could reduce emission by an equivalent 0.4–10.0 gigatons of CO<sub>2</sub> in 2020. These cuts would help to narrow the 12–14 Gt gap in 2030 between national governments' emissions cuts and what global scenarios specify is needed to avoid a 2°C increase in global temperatures, although, the latest IPCC report emphasises the need to garner global action towards a 1.5°C target (IPCC 2018). In September 2018, Jerry Brown, the governor of California and, Michael Bloomberg, the former mayor of New York City, hosted a Global Climate Action Summit that highlighted the role that could be played by diverse actors such as universities, civil society organizations, businesses and local governments through bottom-up and participatory processes to address climate change (Global Climate Action Summit 2018). The critical role of cities in climate adaptation and mitigation has also been identified in a report by the Urban Climate Change Research Network that identifies pathways to sustainable urban transformations (Rosenzweig *et al.* 2018).

Several approaches for bottom-up futures identify local practices and small-scale sustainability initiatives at varying geographic levels and across sectors. At the global level, the Seeds of Good Anthropocenes and Climate CoLab projects are two examples of such initiatives. The Seeds of Good Anthropocenes project is developing a collection of local, social, technological, economic, ecological and social-ecological initiatives to help envision positive environmental futures (Bennett *et al.* 2016). Climate CoLab is an online platform for anyone to submit and discuss climate change solutions (Malone *et al.* 2017). While the Seeds of Good Anthropocenes project focuses on the identification and investigation of the practices of local initiatives, Climate CoLab focuses primarily on the process of initiative identification, development and evaluation through a crowdsourcing mechanism. An example of a sector-specific global database is the World Overview of Conservation Approaches and Technologies (WOCAT). The WOCAT network was established in 1992 to compile, document, evaluate, share, disseminate and apply knowledge for sustainable land management (WOCAT 2018). It was a trendsetter in recognizing the vital importance of sustainable land management and the pressing need for corresponding knowledge management. In early 2014, it was officially recognized by the United Nations Convention to Combat Desertification (UNCCD) as the primary recommended database for best practices in sustainable land management.

Regionally, three European Union projects, namely TESS, TRANSMANGO and PATHWAYS, have also collected local initiatives on a variety of environmental themes. TESS developed a database of small-scale social innovation initiatives in Europe focused on climate change (TESS 2018), while TRANSMANGO focused on food sustainability (TRANSMANGO 2018), and PATHWAYS developed a database on local and regional transitions for a sustainable, low-carbon Europe (PATHWAYS 2018).

The Seeds of Good Anthropocenes initiative calls for “seed-based” scenarios in which collected bottom-up initiatives are scaled up, out and deep (Bennett *et al.* 2016), with the first activities recently completed (Lundquist *et al.* 2017; Pereira *et al.* 2018b). Climate CoLab and TESS do not explore initiatives through scenarios explicitly, but Climate CoLab has conducted experiments in which the public has been invited to integrate local proposals to create national-level climate action plans for many countries and regions of the world (Malone *et al.* 2017). Meanwhile, TRANSMANGO and PATHWAYS have built bottom-up scenarios. The TRANSMANGO project based these on 18 case studies to explore local future pathways to sustainable food systems. By contrast, PATHWAYS integrated knowledge from its database into its development and analysis of transition pathways, but did not base these pathways on combinations of initiatives. While there are a variety of databases of bottom-up initiatives that could be used for building bottom-up or seeds-based scenarios, no global scenarios relevant to all aspects of environmental change are specifically based on such seeds. Methodologies from the Seeds of Good Anthropocenes and TRANSMANGO (Hebinck *et al.* 2016; Hebinck *et al.* 2018; Pereira *et al.* 2018a) provide a starting point for developing such bottom-up global scenarios. The related literature on bottom-up planning and decision-making (Fraser *et al.* 2006; Reed, Fraser and Dougill 2006; Reed 2008; Kuramochi, Wakiyama and Kuriyama 2016; Nemoto and Biazoti 2017) and crowdsourcing (Wiggins and Crowston 2011; Gellers 2015; Vasileiadou, Huijben and Raven 2016), provide useful guidelines for the methods used in this chapter.

### 23.5 Methodological rationale and approach

Part of the conceptual basis for this chapter is the notion that global integrated assessments and bottom-up processes drawing on innovative practices have complementary benefits, and that their connection offers unique insights (**Table 23.1**). As outlined in Chapter 22, global, quantitative simulations of pathways towards the SDGs have the benefit of offering a strong numeric understanding of the global changes needed to reach these goals, and of unexpected positive and negative impacts that attempts to create these changes may have. Such global pathways also have the benefit of offering a context whereby global drivers of change—like those captured by the no-intervention scenarios presented in Chapter 21—can be considered. As a complementary approach to these global assessments, this chapter assesses three complementary modes of analysis:

- i. an assessment of existing platforms featuring bottom-up sustainability initiatives;
- ii. the assessment of local practices through illustrative examples of crowdsourcing and participatory approaches; and

- iii. analysing sub-global interventions for shifting to more sustainable futures, as highlighted by sub-global/regional assessments (Figure 23.1).

The analysis of local-level initiatives offers to support global pathways in tangible examples and mechanisms for change – especially when based on initiatives that are already occurring, even if in pilot or niche form. Sub-global assessments offer regional specificity while still providing broadly applicable meso-level context for national and local pathways.

## 23.6 Investigating the broad landscape of bottom-up initiatives

The broader landscape of bottom-up initiatives not captured in the participatory processes is diverse, but methods for capturing this diversity are limited due to data availability. A range of platforms that collate a variety of environment- and sustainability-related bottom-up initiatives has been identified through an online search and coded. While not exhaustive, Annex 23-1 provides a sample of around 20 bottom-up initiative

**Table 23.1: Different types of assessment model**

|                                           |                                                                                                                                                                                                                                      |

| <b>Synthesis of local practices</b>       | <ul style="list-style-type: none"> <li>❖ Populating macro-level interventions with the 'who and how' – the many actors and innovations that provide feasibility to global and regional pathways</li> </ul>                           |

**Figure 23.1: Outline of how this chapter's bottom-up approaches complement the top-down findings of Chapters 21 and 22 and how together they can offer policy insights for Chapter 24**

platforms. These were identified through Internet searches using keywords that included “sustainability platform” and “bottom-up environmental initiatives” as well as through prior knowledge of initiatives. These platforms are led by a range of both non-government and government actors and provide a preliminary understanding of the breadth and range of ideas, actions and programmes that seek to implement and to help achieve sustainable development objectives.

## 23.7 GEO-6 participatory initiatives

Two participatory processes were organized to develop bottom-up pathways focusing on concrete system transformations. These pathways were developed to complement global integrated assessment models and are based on a diversity of potentially transformative on-the-ground practices and knowledge. These pathways also help to connect GEO-6 to stakeholders globally. The first participatory process was a series of workshops held in Bangkok, Guangzhou, Nairobi and Singapore, where local stakeholders were invited to envision specific transformation pathways based on local practices, within the frameworks of the three pathways of Roads from Rio+20 (PBL Netherlands Environmental Assessment Agency 2012): global technology, decentralized solutions, and lifestyle change (UNEP 2017a; UNEP 2017b; UNEP 2017c; UNEP 2018). The second participatory process was an online contest held in conjunction with the Climate CoLab platform (see **Figure 21.9: Global mean temperature increase**; Climate CoLab 2018). The contest asked participants to combine existing proposals within the Climate CoLab platform to build creative combinations of actions that can achieve climate change goals alongside other SDGs.

As a new and innovative aspect of GEO-6, this chapter and the participatory initiatives offer an illustrative assessment of how participatory actions can add stakeholder perspectives and on-the-ground knowledge to integrated assessment models. This analysis therefore has two goals: (1) it helps to link bottom-

up and top-down perspectives on transformative systemic change for future GEO reports, and, (2) it provides insights on potentially impactful existing practices that could help to achieve transformative change towards sustainability.

From the four workshops and the Climate CoLab contest, three different types of data were gathered: innovative practices and concepts (called seeds), a combination of seed ideas into larger proposals that focused on specific system changes, and Climate CoLab proposals (these are proposals that combined existing ideas within the platform in new and innovative ways). Seeds are examples of existing, but not yet dominant social initiatives, new technologies, economic tools or social-ecological projects, or organizations, movements or new ways of acting that appear to be making a substantial contribution towards creating a future that is just, prosperous and sustainable (Pereira *et al.* 2018a). The workshops collected seeds and asked participants to build proposals for how to achieve as many SDGs as possible by combining those seeds with one another and exploring how they could interact (UNEP 2017a; UNEP 2017b; UNEP 2017c; UNEP 2018). Both the seeds and the combined proposals were framed around one of the three Roads from Rio+20 pathways mentioned above (See PBL Netherlands Environmental Assessment Agency 2012 and Chapter 22). The four workshops led to 156 seeds and 24 proposals for specific system transformations; and the Climate CoLab competition led to 70 proposals, from which judges selected 34 semi-finalists, 12 finalists and two winners (one selected by public vote and one by the judges see **Figure 21.9: Global mean temperature increase** and **Box 23.4**).

To assess the outcomes of the participatory process, the seeds and the Climate CoLab semi-finalist proposals were coded along the five dimensions summarized in **Table 23.2**. These dimensions were selected to best capture the diversity of results and to integrate results with Chapter 22. As an iterative and participatory process, seeds and proposals were coded based on the availability and quality of the data submitted, so

### Box 23.2: Climate CoLab

Climate CoLab is an online contest platform and community run by the Massachusetts Institute of Technology (MIT) Center for Collective Intelligence, with the goal of harnessing the collective intelligence of thousands of people from all around the world to address global climate change. People work on the platform with each other and with over 800 experts on climate change and related topics, to create, analyse and select detailed proposals for what to do about different aspects of the climate change problem. The Climate CoLab site has over 100,000 registered members and has received over 2,500 proposals.

The contest, given the title Exploring Synergistic Solutions for Sustainable Development, began accepting submissions on November 1, 2017, and invited anyone to submit proposals answering the question: “What combinations of Climate CoLab proposals could help achieve multiple SDGs?”

The judges’ contest was promoted through a wide range of networks, including through UN Environment, MIT and other organizational partners worldwide, as well as being promoted to the Climate CoLab community itself. The judges selected 12 finalists plus a judges’ choice winner out of these. The global public was also invited to vote for the proposal most deserving of a popular choice award out of the 12. These winners were announced on 15 March 2018 (See **Box 23.4**).

Contest statistics:

- ❖ 73 proposals submitted
- ❖ 112 proposal authors (individuals or as part of a team)
- ❖ 188 proposal comments submitted by experts, authors and other members
- ❖ 3,064 valid votes cast

See the contest web pages at: <http://www.climatecolab.org/contests/2017/exploring-synergistic-solutions-for-sustainable-development>

**Table 23.2: Coding dimensions**

| Dimension                                                | Categories                                                                                                                                                                                                                                                                                                                                                                                                                             | Description                                                                                                                                                                                                                                                                                                                       |
|----------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Initiative benefits</b>                               | 17 SDGs                                                                                                                                                                                                                                                                                                                                                                                                                                | Coding by SDGs captures the range of benefits for each of the seeds and proposals. Results identify the diversity of outcomes and potential SDG synergies.                                                                                                                                                                        |
| <b>Global measures category</b>                          | 41 global “measures” or “interventions” (as referred to in this chapter when describing specific initiatives) broken down into five system-focused clusters                                                                                                                                                                                                                                                                            | Results were categorized under the 32 measures identified in Chapter 22 along with nine additional interventions, identified during the coding process, that did not fit neatly under any of the existing 32 measures. The clusters for freshwater and for oceans were grouped together due to low representation in the results. |
| <b>Theory of change</b>                                  | <ul style="list-style-type: none"> <li>❖ New technology</li> <li>❖ Decentralization</li> <li>❖ Design/infrastructure</li> <li>❖ Monitoring and reporting</li> <li>❖ Change in production practices</li> <li>❖ Lifestyle change</li> <li>❖ New organization/business</li> <li>❖ Knowledge/data platform</li> <li>❖ Policy change</li> <li>❖ Finance/incentives/subsidies</li> <li>❖ Awareness, knowledge, skills development</li> </ul> | The theory of change identifies the type of change or solution of the initiative. These categories are based on an iterative coding process of results to best capture the diversity while minimizing overlapping categories.                                                                                                     |
| <b>Actor</b>                                             | <ul style="list-style-type: none"> <li>❖ International organizations</li> <li>❖ Governments (local, regional, national)</li> <li>❖ Private sector/businesses</li> <li>❖ Civil society</li> <li>❖ Academic and research institutions</li> <li>❖ Households/individuals</li> </ul>                                                                                                                                                       | The type of actor focuses on their involvement in each of the initiatives.                                                                                                                                                                                                                                                        |
| <b>Geography (only for Climate CoLab semi-finalists)</b> | <ul style="list-style-type: none"> <li>❖ By country</li> </ul>                                                                                                                                                                                                                                                                                                                                                                         | The country or countries where the initiative would be deployed and where the authors originated.                                                                                                                                                                                                                                 |

not all the results could be coded on all dimensions. It should also be noted that some dimensions were self-identified by the contributors, while others were specifically coded by the GEO author team.

## 23.8 GEO-6 Regional Assessments

Six GEO Regional Assessments were completed in 2016: for Africa, Asia and the Pacific, Europe, Latin America and the Caribbean, North America, and West Asia. These can be viewed as intermediate assessments between global and local assessments. Each Regional Assessment highlights region-specific environmental challenges and the key interventions for addressing them. When viewed together, these assessments provide a global set of overarching challenges and responses for securing a more sustainable future that still retain certain regional priorities. In this chapter, we compare the key interventions identified in the six regions with those identified from the review of the scenario literature (Chapter 22) and the bottom-up processes (Figure 23.15). By doing so, we aim to identify potential gaps in the interventions considered at all three levels of assessment (global, regional and local), and to draw insights that enhance the range of interventions and policy options available to decision makers.

In a similar way to participatory initiatives, key interventions identified in the Outlook chapters of the GEO Regional Assessments were coded according to the interventions

identified by the review of the scenarios literature (Chapter 22, Table 22.1). Interventions that were not on the predefined list from the scenario literature review were added to derive an updated list of interventions.

## 23.9 Findings from a bottom-up approach

### 23.9.1 Broader bottom-up platforms and the diverse actors needed for change

National governments throughout the world have begun to recognize that sound climate scenario modelling and assessment require contributions from bottom-up sources (Hsu *et al.* in press). Global emissions trajectories modelled from top-down integrated assessment models (van Vuuren *et al.* 2011) do not explicitly incorporate information from bottom-up initiatives and individual contributions from local governments, businesses and civil society organizations. Top-down emission pathways assume that these mitigation efforts are subsumed into national government pledges, but bottom-up actors make climate commitments that could be considered additional to or outside of national climate efforts, complicating the assessment of climate mitigation scenarios (Hsu *et al.* 2015; Jordan *et al.* 2015). Compounding this complexity, individual actors frequently form hybrid coalitions, often in cooperation with national governments, building transnational climate governance networks. These partnerships demonstrate the potential additive effects of individual bottom-up climate

actions when actors align targeted goals and coordinate efforts (Andonova, Betsill and Bulkeley 2009).

In December 2014, the United Nations Framework Convention on Climate Change (UNFCCC) launched the Global Climate Action portal (also known as NAZCA after its former name, the Non-state Actor Zone for Climate Action) in an effort to capture and track the diversity of bottom-up actors and commitments pledging climate mitigation, adaptation, financing, capacity-building and other actions to address climate change (UNFCCC 2018; see **Box 23.3**). The Global Climate Action portal was initially developed to illustrate an 'all hands on deck' approach (Hale 2016) to climate governance, and the scientific and analytical community is now moving towards a consistent methodology to account for quantifying bottom-up actor contributions in global climate mitigation scenarios (Initiative for Climate Action Transparency [ICAT] 2018; Hsu *et al.* in press). This effort is intended to serve multiple objectives:

- i. quantifying the global aggregation of bottom-up climate efforts and its additional impact in existing climate scenarios will allow for more accurate appraisal of existing emission pathways and gaps.
- ii. understanding the mitigation contributions of bottom-up efforts will provide national governments with additional information by which to leverage more ambitious Nationally Determined Contributions to the Paris Climate Agreement in review cycles (UNFCCC 2015). This knowledge of decentralized impacts could also prompt and enable governments to better support and scale up these activities.
- iii. incorporating bottom-up initiatives into global climate scenarios will provide recognition of small-scale initiatives or qualitative contributions (e.g. capacity-building) that are critical to advancing lower-carbon trajectories but are difficult to quantify (Chan, Brandi and Bauer 2016).

#### **Results from the analysis of bottom-up platforms**

Over 50,000 individual bottom-up actions were identified, but their different structures and goals made comparisons challenging. Evaluating platforms, rather than individual commitments, helped to facilitate comparisons between different kinds of bottom-up action, and also to shed light on the structures in place to enable and support the continued growth and development of these initiatives. The platforms identified through the online search range from the Amazon Vision Coordination and Information Platform, which is based

in Colombia and includes more than 200 initiatives that support the implementation of mitigation activities against greenhouse gas emissions (GHG), to Sustainia 100, which has tracked more than 4,500 sustainable solutions being deployed by 188 companies. The aims of these platforms vary, from providing crowdsourcing solutions to listing microfinancing options, to giving information that connects stakeholders (**Figure 23.2**). Platforms often seek to support or feature initiatives from a wide range of actor types while others have a narrower focus on a particular type of actor, such as business. Drawing examples from all over the world, all but five platforms have a global level of coverage. The five non-global initiatives focus on city (MTLGreen), regional (Amazon Vision Coordination and Information Platform, MACBIO – Pacific) and national (e.g. WorthWild, GreenCrowd) issues.

The majority of the platforms considered, facilitated knowledge-sharing and the identification of solutions in two ways. One was through the collection of examples, solutions and best practices (e.g. UNFCCC Momentum for Change Lighthouse Initiative, PANORAMA Solutions for a Healthy Planet), and the second was by creating forums for sharing technical or regional tools and know-how, to support a wide range of on-the-ground activities (e.g. Biofin Knowledge Platform, ClimateTechWiki). Still other platforms used contests or crowdsourcing to generate and synthesize solutions to challenging questions (e.g. VertMTL, MIT Climate CoLab). Fewer platforms focused on tracking the progress or impacts of activities (e.g. REDDX) or on enabling project implementation by matching projects with funds or other forms of technical or capacity support (e.g. WorthWild, Greencrowd, Divvy, LifeWeb Initiative).

The coding analysis revealed a wide variety of actors working at all scales to implement the SDGs (**Figure 23.3**). The platforms we identified are convened, curated or led mainly by a range of non-government and government actors, and primarily facilitate knowledge-sharing and the identification of solutions between bottom-up initiatives. These spaces may provide an important route for scaling solutions out, and could lay the foundations to scale solutions up, by collecting and distilling best practices and innovative solutions. Creating forums for collaboration and exchange may also help to facilitate loose coordination and a mutually beneficial division of labour between different actors. Abbott's (2012) research on transnational initiatives, for example, finds that many coalitions perform activities that national governments may be less suited to implement, such as information-sharing and capacity-building.

#### **Box 23.3: The Global Climate Action portal**

The Global Climate Action portal, also known as NAZCA, is an online platform currently featuring more than 12,000 commitments to climate change action made by local governments, businesses, civil society organizations, higher education institutions and investors. These range from individual companies adopting internal carbon prices to constrain emissions growth, to city governments pledging carbon neutrality. The Global Climate Action portal also includes initiatives like the World Food Programme's R4 Rural Resilience Initiative (World Food Programme 2018), which aims to increase resilience to climate change through an integrated risk management system for 100,000 farmers. By far the most numerous bottom-up actor types in the portal are subnational and local governments, with close to three-quarters of cities in the platform located in Europe (Hsu *et al.* 2016). This geographic overrepresentation of bottom-up actors in the global North, due to a lack of reported data, is one of the major limitations of efforts to understand the scope of climate action. The vast majority of the climate commitments are focused on emission reduction targets, with 85 per cent of subnational efforts and close to 40 per cent of corporate actions addressing climate mitigation. Most of the actions in the Global Climate Action portal recognize the role of local efforts to promote clean energy production and alter the consumption systems that are responsible for global climate change.

**Figure 23.2: The number of initiatives covered in a sample of platforms that feature bottom-up sustainability initiatives (see Annex 23-1 for a brief description of the platforms)**

**Figure 23.3: The SDGs represented proportionally by how they are covered by the selected bottom-up sustainability initiative platforms. Some initiatives are narrower in scope and strictly relate to one, two or three SDGs, while others are diverse and capture a wider range of SDGs (four or more) (see Annex 23-1 for a brief description of the initiative platforms)**

### 23.9.2 Participatory processes

While Section 23.10 outlines the array of platforms that are already collecting initiatives with the potential to help meet the 2030 Agenda for Sustainable Development, this section presents results from the participatory workshops and Climate CoLab crowdsourcing that further bring to light the diversity of solutions found globally. These initiatives were identified as concrete examples of typical solutions in the measure categories outlined in Chapter 22. They also challenge some of the assumptions of how change happens within top-down models, and highlight the interrelated trends of SDGs, their potential synergies, and the role of diverse actors in achieving the 2030 Agenda – while the top-down models help focus on trade-offs. This section first provides an overview of trends found across all workshop seeds and Climate CoLab proposals before breaking down the results by the four clusters studied in Chapter 22. In addition, a fifth cluster of measure/intervention categories was created based on the solutions found in the bottom-up work that did not neatly fit within those four existing clusters – these are discussed more fully in Section 23.10. The assessment demonstrates the potential of bottom-up initiatives to aid policymakers and top-down analyses, but, due to the limited sample size it does not present a comprehensive overview of all on-the-ground solutions globally.

## General landscape of initiatives

### SDGs

The workshop seeds and Climate CoLab proposals targeted all 17 SDGs to varying extents. **Figure 23.4** highlights the range of SDGs that were found in the analysis. In the case of the workshop seeds, SDG 12 (responsible consumption and production) and SDG 11 (sustainable cities and communities) were most represented. As for Climate CoLab proposals, SDG 13 (climate action) was targeted by over 80 per cent of proposals, followed by SDG 3 (good health and well-being).

### Actors

Workshop seeds focused most on government actors, private sector/business and households/individuals (**Figure 23.5**). Over 60 per cent of workshop seeds indicated a role for the government, with local government mentioned most, followed by national governments. Similarly, Climate CoLab proposals also emphasized the role of government, with national governments being referenced most. The importance of assessing diverse actors is elaborated further in Section 23.11.

### Geography

In submitting proposals on the Climate CoLab platform, contributors were requested to identify up to five countries where their proposals would be active (**Figure 23.6a**).

Within the 34 Climate CoLab semi-finalists the individual countries that were most covered were the Republic of Kenya (11 proposal mentions), the Republic of India (8) and the United Republic of Tanzania (7). As an open and global crowdsourcing project for solutions, the emphasis on the global South points towards a geographical inequity about where change is perceived to be needed, and highlights a need for transformations to be more equitable across regions (see Section 23.14 for a discussion on distributive justice and equitable transformations). Some of the solutions emanated from the global North for application in the global South making the case for equity particularly relevant. Although not deliberate, this trend can be seen to reinforce the narrative that the North can continue on a business-as-usual trajectory while the South develops more sustainably, and also misses out some of the nuance of how contextual the interpretation of sustainability is and how to achieve it (see Vercoe and Brinkman 2009). However, the high number of suggestions made by contributors from the Global South (**Figure 23.6b**) also points to the innovative thinking that is happening in these parts of the world, where the urgency for action towards meeting Agenda 2030 is greater (Nagendra 2018). By enabling contributions from across the globe, the participatory processes of GEO 6 could capture a range of context-specific solutions for achieving sustainable development.

### Theory of change

Seeds and Climate CoLab proposals overwhelmingly focused on new technologies to reach their desired goals (**Figure 23.7**). Climate CoLab proposals also largely emphasized changes in production practices, thus making producers more responsible for sustainability interventions. Seeds focused more on lifestyle change and putting the responsibility on consumers rather than producers. Within the 'new technology category' there was also a large emphasis on app-based solutions. Eleven seeds and one Climate CoLab proposal proposed apps, largely to enable users to monitor and report on sustainability issues and to connect with others over them. These included the Climate CoLab proposal to enable urban dwellers to report on the quality of their environment (C'SQUARE), and seeds like a plastic waste footprint calculator app or apps to report water pollution to relevant authorities, monitor energy consumption, help report and identify plants, and several sharing economy apps related to ride-sharing, waste exchanges, and product borrowing from neighbours. The winning Climate CoLab proposals had technological innovations at their core: ClimateCoop was based on blockchain technology and The Community-Based Framework for Sustainable Development integrated existing technologies to meet multiple sustainability needs holistically (For an example see **Box 23.4**).

### Clusters within workshop seeds and Climate CoLab proposals

Workshop seeds and Climate CoLab proposals were coded by types of intervention and broad clusters, according to the categories outlined in **Table 22.13** in Chapter 22. The cluster coding allows for the bottom-up initiatives to complement and reinforce the top-down analysis. As the bottom-up approaches are new to GEO-6, the following discussion is intended to be illustrative of the possibilities offered by these complementary methods. In future assessments, a larger data set could be gathered, and results linked more explicitly to the top-down efforts, and, in turn, the top-down analysis could be enhanced by including some of the findings from the bottom-up analysis. Coding was done by subjectively assigning as many intervention types as were appropriate, based on the description provided for each seed or Climate CoLab proposal; as such, it is common for multiple intervention types across more than one cluster to be represented in a given proposal. Due to low representation in the two clusters of freshwater and oceans, these have been grouped together throughout this chapter for cluster-based analysis and based on the original cluster in Chapter 22. However, it is recommended that freshwater and oceans are considered separately in future assessments.

**Figure 23.7: How each theory of change is represented by the total seeds and proposals**

### ClimateCoop - The Climate Consortium Blockchain (Judges' Choice Winner)

ClimateCoop is a blockchain-based platform that allows for decentralized, local, and transparent action on SDGs. This distributed platform connects interested parties (e.g. individuals, researchers, sponsors, international organizations, governments, businesses) and facilitates collaborations for new ideas and initiatives. On the platform, initiative creators can update their progress, while accredited members can review and approve future initiatives. The developers of the ClimateCoop Platform believe that their innovation utilizes the best of distributed digital technology, modern social patterns, decentralized matrix governance, and disruptive economic models (e.g. crowdsourcing) to efficiently support bottom-up climate and sustainability action. Their platform empowers individuals and institutions to cooperate and collaborate.

### Framework for Community-Based Sustainable Development (Popular Choice Winner)

The Framework for Community-Based Sustainable Development introduces a comprehensive, integrated roadmap for communities to pursue sustainable development. This integrated roadmap builds upon the energy, water/waste, and food sectors to create a holistic approach to community sustainability. By emphasizing the synergistic nature of infrastructure and society, this roadmap helps future development consider the "human factor" within sustainability, ensuring environmental sustainability that is community inclusive. The framework's independent components such as the development of biogas technology, vertical hydroponic farms, and rainwater harvesting are designed to be adaptable to different localities.

Source: Wright, Yang and Ma (2018).

**Figure 23.8** shows that in the workshop seeds, there was strong representation of the energy, climate and air cluster, particularly linked to SDGs 7, 11 and 13. Specific interventions within the cluster are detailed below, but popular interventions related to low/zero emissions, behaviour change, energy efficiency and (to a lesser degree) energy access. The seeds showed strong representation of the various categories described as “other” (not part of the main cluster groupings identified in Chapter 22), particularly awareness and skills building, monitoring and reporting, plastics and consumer waste reduction, and circular economy, with the strongest SDG links being to SDGs 11 and 12, with slightly less strong links to SDGs 3 and 13. There was modest interest in the food, agriculture, land and biodiversity cluster, with the strongest interventions relating to diet change and protection of terrestrial ecosystems. Due to the participatory workshops taking place in cities, there was a big focus on how to meet SDGs in an urban context – **Box 23.5** provides some of these key findings from the interventions that emerged in the participatory processes.

### Box 23.5: Urban systems

GEO-6 identifies urbanization as one of five key drivers of environmental change, creating fundamental changes in natural and social systems, as well as one of 12 cross-cutting issues that require urgent and systemic responses (see Chapters 2 and 4). With around 60 per cent of the urban areas yet to be built to accommodate the urban population of 2050, it is critical to ensure that urban systems designed today are made as sustainable as possible.

The participatory results focused to a large extent on improving urban environments, with SDG 11 (sustainable cities and communities) mentioned often, by 38 per cent of all workshop seeds and half of all Climate CoLab proposals. Analysis of these results also showed a variety of SDG synergies, supporting the idea of urbanization being a cross-cutting issue in which solutions can have multiple co-benefits. Seeds addressing SDG 11 had large synergies for addressing SDGs 3, 9, 12 and 13. Climate CoLab proposals also indicated several synergies with SDG 11, including for SDGs 3, 12, 13 and 17. These coding results were further reflected in the descriptions of relevant seeds and proposals, as many spoke of a variety of co-benefits for urban-based solutions.

Urban-related seeds often focused on empowering citizens using online platforms and smartphone applications. Some apps focused on allowing users to monitor and report their energy usage, air and water pollution, to identify plant species (biodiversity), and more. A core aspect of these apps was to enable data-based action in addition to educating users. An app to monitor energy consumption incorporated monetary incentives to change electricity use habits, and an app to monitor water quality connected directly to relevant municipal water agencies. Urban seeds also focused on infrastructure, particularly on developing green infrastructure through green roofs, community gardens and green building standards more generally.

In all four workshops, seeds-based visions often coalesced around sustainable cities or communities. Urban areas were imagined in which buildings are fitted with solar panels and/or green roofs, are built with sustainable materials, and make use of smart technologies to minimize energy usage. Pathways to sustainable futures often included setting aside spaces and providing infrastructure to enable urban agriculture, the products of which could be used for food as well as for sustainable consumer goods such as biodegradable or edible cutlery. One pathway focused specifically on an international cities platform that allows for environmental data and actions to be aggregated internationally, and to be used by citizens to learn and engage in sustainable community actions.

**Figure 23.8: Heat map of workshop seeds, showing pairings of specific measures/interventions and SDGs**

| Cluster                                  | Measure category                              | No poverty (1) | Zero hunger (2) | Good health and well-being (3) | Quality education (4) | Gender equality (5) | Clean water and sanitation (6) | Affordable and clean energy (7) | Decent work and economic growth (8) | Industry, innovation and infrastructure (9) | Reduced inequalities (10) | Sustainable cities and communities (11) | Responsible consumption and production (12) | Climate action (13) | Life below water (14) | Life on land (15) | Peace, justice and strong institutions (16) | Partnership for the goals (17) |

Numbers indicate the count of proposals coded with the specific pairing of intervention (row) and SDG (column). 'Other' is described more in Section 23.11

The cluster groupings were quite different between the seeds and the Climate CoLab proposals. In the latter, agriculture, food, land and biodiversity emerged as a very strong cluster, far more so than in the workshop seeds, with many Climate CoLab proposals targeting food access and minimizing land damage (Figure 23.9). Climate CoLab proposals also focused heavily on poverty alleviation. The added intervention type, awareness and skills building, was strongly represented in both the seeds and Climate CoLab proposals. SDGs 1, 2, 3 and 13 emerge as strongly linked across many proposals. Comparatively few Climate CoLab proposals had interventions relating to energy, climate and air despite strong representation of SDG 13 (climate action). Gender equality emerged as a strong

intervention in Climate CoLab proposals compared with the seeds, but it was not strongly related to any other SDG. Neither the seeds nor the Climate CoLab produced any substantial focus on the merged cluster for freshwater and oceans, although this gap is partially addressed in the analysis of the Regional Assessments.

Figure 23.10 shows the number of seeds/proposals that sit across multiple clusters. The Climate CoLab proposals were more likely to be relevant in more than one cluster, whereas the seeds tended to stay within one cluster. This makes sense because the seeds were typically single initiatives rather than a combination of interventions into one proposal. Seeds show

a tendency to pair energy, climate and air with the “other” cluster, while in the Climate CoLab proposals, this pairing is one of the least common. The Climate CoLab proposals are far more likely to show pairings between various clusters and human well-being due to the strong representation of poverty alleviation across the Climate CoLab proposals. The key conclusion from this figure is that, when looking at real-world examples, it is possible for interventions to work across clusters. It is therefore also possible to give specific example of how to achieve the synergies described in Chapter 22.

#### Agriculture, food, land and biodiversity

Seeds and Climate CoLab proposals within the cluster for agriculture, food, land and biodiversity were most related to food access, protection of terrestrial ecosystems, and minimizing land damage (Figure 23.11). No solutions targeted land ownership, and only two addressed nutrition management.

Some key trends emerging from this cluster are the decentralization and localization of food production (e.g. community-supported agriculture, urban farming innovations) to improve food access, minimize land damage and potentially improve yields. These types of solution could potentially

address the yield-improvement trade-offs that were identified by Chapter 22, for example against addressing climate change and water scarcity.

#### Energy, climate and air

Seeds and proposals that fit within the energy, climate and air cluster were most related to low- or zero-emission technologies, behavioural change in the use of transport and household energy, energy access, and improved energy efficiency (Figure 23.12). Bioenergy, negative-emissions technologies, and air-pollution control were addressed very sparsely. One of the Climate CoLab proposals “Adapting the indigenous approach to climate change adaptation and mitigation” makes clear the importance of not relying only on technological fixes, but recognising the relevance of local innovations that draw on a variety of knowledge sources.

#### Freshwater and oceans

The clusters for freshwater and oceans, combined for the analysis, were among the least-addressed ones, especially in Climate CoLab proposals (Figure 23.13). Seeds within this combined cluster focused most on WASH (water, sanitation and hygiene) while no seeds or proposals addressed desalination or ocean regulation.

**Figure 23.11: Total number of workshop seeds and Climate CoLab proposals addressing each intervention in the agriculture, food, land and biodiversity cluster (seeds and proposals are double counted when they meet multiple measures)**

**Figure 23.12: Total number of workshop seeds and Climate CoLab proposals addressing each intervention in the energy, climate and air cluster (seeds and proposals are double counted when they meet multiple measures)**

**Figure 23.13: Total number of workshop seeds and Climate CoLab proposals addressing each intervention in the combined clusters for freshwater and oceans (seeds and proposals are double counted when they meet multiple measures)**

## Human well-being

Solutions related to human well-being focused predominantly on the alleviation of poverty while child and maternal health-care was addressed by only one Climate CoLab proposal (**Figure 23.14**). This could highlight an important area for government interventions to specifically target these areas.

## 23.10 GEO Regional Assessment synthesis

The additional interventions highlighted by the GEO-6 Regional Assessments are presented below, followed by an outline of the main regional emphasis of different clusters of interventions, and a comparison with the prevalent top-down and bottom-up interventions.

### 23.10.1 Relevance of additional interventions for different regions

Nine additional interventions were highlighted in the Regional Assessments (see Section 23.11 for a more in-depth discussion). Two of these – effective governance, and awareness and skills building – were highlighted as important interventions across all six Regional Assessments. The Regional Assessments indicate the need to involve a diverse range of actors in seeking transformative solutions to achieve sustainable development, and all of the regional assessments emphasize the development of new collaborations between business, government and civil society. In addition to these commonalities, the assessments strongly reflected region-specific issues, which emphasizes the need for considering bottom-up initiatives. In North America, the identified governance and capacity-building needs focused on integrated forward-looking approaches that leveraged new technologies and citizen science in monitoring and reporting that would ultimately internalize environmental costs in the economy. Africa and Latin America and the Caribbean emphasized effective implementation and regulation to prevent further habitat loss and land degradation, focusing strongly on policies that strengthen equitable landownership and sustainable use of natural resources. Europe, and Asia and the Pacific strongly emphasized regional policy integration and cooperation, although the outlook for Europe focused its policy coordination around encouraging sustainable lifestyles,

while Asia and the Pacific emphasized coordination as an adaptation response in disaster risk reduction. In West Asia, the dominant governance issue was peace and security. Only three assessments (Africa, Europe, and Latin America and the Caribbean) emphasized the need for global governance in addressing tele-coupling aspects that transfer the impacts of production and consumption to other regions. This limited consideration of interregional impacts, particularly from major regions of consumption such as North America and parts of Asia and the Pacific, is concerning and should be included as an explicit criterion in future Regional Assessments.

Monitoring and reporting, plastic and consumer waste reduction, and ecosystem restoration were also prevalent regional interventions that were not originally emphasized in the review of the scenario literature. Monitoring and reporting was emphasized by all regions except Europe, and the focus was on the use of new technologies and citizen science to monitor future trends and report on sustainable development. Plastic and consumer waste reduction was emphasized by most regions – except Africa, and Latin America and the Caribbean – and focused primarily on solutions against landfill being used for solid waste management. Ecosystem restoration was emphasized by Europe, North America and West Asia, but the focus differed in each region. In North America, restoration was considered important for improved water-quality management, while in West Asia restoration was strongly focused on restoring coastal marine ecosystems as a strategy to reduce disaster risk. In Europe, restoration was an integrative pathway to realizing multiple goals for biodiversity conservation, the rewilding of abandoned farmlands, a reduction of nitrogen and GHG emissions, and the mental and physical health benefits of restoring blue-green infrastructure.

Circular economies and smart cities for sustainability were highlighted as interventions by only some of the Regional Assessments (**Figure 23.15**). Nevertheless, at least two regions identified these as priority interventions, and there are indications from the bottom-up initiatives that these interventions represent emerging opportunities that can be leveraged as integrated and synergistic approaches to achieve sustainable futures.

**Figure 23.14: Total number of workshop seeds and Climate CoLab proposals addressing each intervention in the human well-being cluster (seeds and proposals are double counted when they meet multiple measures)**

Blue indicates that the intervention was highlighted by the associated regional assessment for moving towards a more sustainable development trajectory; white indicates absence of the intervention. The interventions are clustered similarly to the grouping used in Chapter 22. Interventions that were not on the predefined list from the scenario literature review (those labelled "Other regional and bottom-up interventions") were added to derive an updated list of interventions (see Section 23.8).

### 23.10.2 Regional emphasis of different clusters of interventions

The most frequently occurring interventions across regions were low/zero-emission technologies, the protection of terrestrial biodiversity, effective governance, skills and awareness building, and monitoring and reporting. The Regional Assessments highlighted roughly similar proportions of interventions in the energy, climate and air cluster and in the agriculture, food, land and biodiversity cluster, with interventions in the combined cluster for freshwater and oceans showing only slightly less prevalence (**Figure 23.16**). There was a marked absence of interventions that directly addressed the human well-being cluster (unlike the Climate CoLab proposals in which this cluster was emphasized heavily). Below the emphasis the regions place on the interventions within the clusters identified in Chapter 22 is discussed.

#### *Energy, climate and air*

A positive finding, also emphasized in Chapter 22, is that renewable energies are on the agendas of all regions. All six assessments – no matter whether primarily comprising developed or developing economies – emphasize renewable energies in their key interventions. In Africa, this is not only viewed as a way of improving air quality and GHG emissions, but also as a means of improving access to basic services by providing off-grid development in rural areas. In West Asia, renewable energies are viewed as a fundamental consideration for food and water security. Even though the GHG emissions in Latin America and the Caribbean are currently the lowest globally, the region places strong emphasis on renewable energies as a means of curbing current trends, which are expected to increase dramatically in the scenarios in which there is no investment in low-carbon futures.

Although renewable energies are on the agendas of all regions, there are clear gaps in interventions dealing with emissions reductions, with Europe being the only region to emphasize the full range of energy, climate and air interventions. This lack of direct action for climate mitigation is concerning. In addressing climate-change adaptation there is a definite regional difference: both Africa and North America emphasize food and water security; Asia and the Pacific, and West Asia emphasize disaster-risk reduction; Europe emphasizes air quality and health; and Latin America and the Caribbean focuses on ecosystem-based resilience and the need systematically to consider alternative sustainability framings that can be found in indigenous and local knowledge.

#### *Agriculture, food, land and biodiversity*

This cluster of interventions reflects the management of the land system, which has conventionally been dominated by ecological and biophysical perspectives. While protection of terrestrial ecosystems still dominates the interventions in this cluster, there are indications that conventional approaches are broadening in scope to include more integrated social-ecological initiatives, such as reduced food waste, yield improvement, agro-biodiversity, and forest and land management (**Figure 23.16**). In Africa and Latin America and the Caribbean, this shift from a protection approach towards more sustainable land management has been reflected in the concept of ecological infrastructure and the complementary

benefits it has for built infrastructure. In all regions, the lack of nutrition management and diet change, however, are notable gaps in the interventions highlighted by the Regional Assessments, indicating that the more behavioural aspects of the social-ecological spectrum have not yet been fully entrenched into this cluster in the regions. Similar gaps in socioeconomic interventions are prevalent in the human well-being cluster.

The interventions in this cluster also reflected region-specific environmental issues. Africa, and Latin America and the Caribbean had a very strong emphasis on protection of terrestrial ecosystems and sustainable land management, reflecting the need to address the enormous pressures these regions face around large-scale land conversion for agriculture. The Africa region, in its focus for leapfrogging to more sustainable development, also highlighted the potential for investment in agricultural intensification to increase efficiencies and improve agricultural yield simultaneously, and thereby minimize further habitat loss. Europe and North America placed strong emphasis on yield improvement and reduced food waste, with Europe also focusing attention on land abandonment and rewilding. Food access was another social intervention that was highlighted in this cluster, and this pertained to providing improved opportunities to smallholder farmers in Africa and West Asia.

#### *Freshwater and oceans*

Like the workshop seeds and Climate CoLab proposals, the Regional Assessments emphasized proportionally fewer interventions in the freshwater and oceans cluster compared with the previous two clusters in this section. The outlooks for Europe, and Latin America and the Caribbean were particularly scant on emphasizing interventions in this cluster. Both regions show signs of improvement in their key freshwater challenges (improved water quality in Europe; improved water supply and sanitation in Latin America and the Caribbean), so there may be more important regional challenges, such as production and consumption changes in Europe, and sustainable land management in Latin America and the Caribbean.

The most frequently emphasized freshwater interventions were integrated water resource management, improved water use efficiency, and water and sanitation. The first two of these are often bundled together, with the predominant narrative being around integrated water resource management to address water scarcity and water allocation issues. This was emphasized by Africa, Asia and the Pacific, and North America (the latter after recent droughts and under climate change projections). Interestingly, West Asia did not emphasize water scarcity in itself, but rather the investment costs of groundwater abstraction and desalination for continued water supply and sanitation of rapidly expanding cities. This indicates that at least one region is explicitly emphasizing diversification of water sources as a feasible response to water supply challenges. Water quality issues – both in terms of safe wastewater treatment and water supply quality – were addressed separately from integrated water resource management. Water quality interventions were emphasized in the Outlooks presented for North America and West Asia, where both regions highlighted issues with wastewater treatment as well as chemical contaminants.

**Figure 23.16: Number of regions emphasizing interventions within the clusters identified in Chapter 22**

|                                          |                                               | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 |
|------------------------------------------|-----------------------------------------------|---|---|---|---|---|---|---|---|
| Energy, Air and Climate                  | Energy access                                 |   |   |   |   |   |   |   |   |
|                                          | Behavioural change (transport and households) |   |   |   |   |   |   |   |   |
|                                          | End-use electrification                       |   |   |   |   |   |   |   |   |
|                                          | Low/ zero emission technologies (non-biomass) |   |   |   |   |   |   |   |   |
|                                          | Bioenergy (with and without CCS)              |   |   |   |   |   |   |   |   |
|                                          | Improve energy efficiency                     |   |   |   |   |   |   |   |   |
|                                          | Negative emission technologies                |   |   |   |   |   |   |   |   |
|                                          | Air pollution control                         |   |   |   |   |   |   |   |   |
|                                          | Non-CO <sub>2</sub> emission reduction        |   |   |   |   |   |   |   |   |
| Agriculture, Food, Land and Biodiversity | Reduce food waste                             |   |   |   |   |   |   |   |   |
|                                          | Yield improvement                             |   |   |   |   |   |   |   |   |
|                                          | Nutrition management                          |   |   |   |   |   |   |   |   |
|                                          | Food access                                   |   |   |   |   |   |   |   |   |
|                                          | Diet change                                   |   |   |   |   |   |   |   |   |
|                                          | Manage soil carbon loss                       |   |   |   |   |   |   |   |   |
|                                          | Minimize land damage                          |   |   |   |   |   |   |   |   |
|                                          | Land ownership                                |   |   |   |   |   |   |   |   |
|                                          | Protection of terrestrial ecosystems          |   |   |   |   |   |   |   |   |
|                                          | Land-use planning                             |   |   |   |   |   |   |   |   |
|                                          | Forest management                             |   |   |   |   |   |   |   |   |
|                                          |                                               |   |   |   |   |   |   |   |   |
| Human Well-being                         | Poverty alleviation                           |   |   |   |   |   |   |   |   |
|                                          | Child/maternal healthcare                     |   |   |   |   |   |   |   |   |
|                                          | Education                                     |   |   |   |   |   |   |   |   |
| Freshwater and Oceans                    | Improve water-use efficiency                  |   |   |   |   |   |   |   |   |
|                                          | Blue carbon                                   |   |   |   |   |   |   |   |   |
|                                          | WASH                                          |   |   |   |   |   |   |   |   |
|                                          | Wastewater treatment                          |   |   |   |   |   |   |   |   |
|                                          | Water quality standards                       |   |   |   |   |   |   |   |   |
|                                          | Desalination                                  |   |   |   |   |   |   |   |   |
|                                          | Integrated water resource management          |   |   |   |   |   |   |   |   |
|                                          | Sustainable fisheries                         |   |   |   |   |   |   |   |   |
|                                          | Ocean regulation                              |   |   |   |   |   |   |   |   |
|                                          | Protection of marine ecosystems               |   |   |   |   |   |   |   |   |
| Other                                    | Monitoring and reporting                      |   |   |   |   |   |   |   |   |
|                                          | Circular economy                              |   |   |   |   |   |   |   |   |
|                                          | Sharing economy                               |   |   |   |   |   |   |   |   |
|                                          | Plastics and consumer waste reduction         |   |   |   |   |   |   |   |   |
|                                          | Awareness and skills building                 |   |   |   |   |   |   |   |   |
|                                          | Gender equality                               |   |   |   |   |   |   |   |   |
|                                          | Smart cities for sustainability               |   |   |   |   |   |   |   |   |
|                                          | Ecosystem restoration                         |   |   |   |   |   |   |   |   |
|                                          | Effective Governance                          |   |   |   |   |   |   |   |   |
|                                          |                                               |   |   |   |   |   |   |   |   |

Clusters identified in Chapter 22 (0 = none, 6 = all regions)

The regional Outlooks for Africa and Asia and the Pacific were the only ones that highlighted interventions for the oceans. For Africa, this was mainly around protecting marine ecosystems for sustainable fisheries. In Asia and the Pacific, protecting marine ecosystems was viewed as a strategy both for sustainable fisheries management and disaster risk reduction, particularly in relation to protection and restoration of mangroves.

#### Human well-being

There was a distinct lack of emphasis placed on the interventions in the human well-being cluster. Only one regional outlook (for Latin America and the Caribbean) identified one intervention (education) as a key intervention for transforming to a sustainable future. The more socially oriented interventions in other clusters were either poorly emphasized (e.g. energy access, food access, smart cities for sustainability), or not highlighted at all (e.g. nutrition management, diet change, poverty alleviation, sharing economy, gender equity and equality). This is not to say that human well-being interventions are ignored throughout the Regional Assessments or even in the chapter presenting the outlook. Indeed, in many cases, the synergies with human well-being SDGs are discussed, and in detail in some cases (e.g. Africa, and Latin America and the Caribbean). However, these are not emphasized as interventions in and of themselves. Instead, the Regional Assessments regarded interventions in this cluster as the fortunate spin-offs of managing the previous three clusters, rather than explicitly planning for synergistic target achievement. Future Regional Assessments could strive for more integrative strategies through explicitly addressing and planning for this cluster of interventions.

## 23.11 Regional outlook interventions and bottom-up initiatives

### 23.11.1 Additional categories of intervention

A large portion of solutions did not fit neatly into any of the categories of measures in Chapter 22 in the process of collecting and assessing the seeds and proposals, and

reviewing the emphasized regional interventions (see "other" in **Figures 23.15** and **23.16**).

As a result, nine new categories were developed and coded as part of the analysis:

- ❖ **Monitoring and reporting:** Innovations to improve the monitoring and reporting of environmental conditions, including citizen science initiatives.
- ❖ **Circular economy:** Innovations that involve the increased efficiency of resource use, specifically through new business models that better engage with the issue of waste products of other production processes (See Ghisellini, Cialani and Ulgiati 2016).
- ❖ **Sharing economy:** Innovations related to the peer-to-peer sharing of goods and services, primarily through information and communications technology (ICT) platforms (See Hamari, Sköklint and Ukkonen 2016).
- ❖ **Plastic and solid waste reduction:** Innovations that help to reduce plastic and solid waste.
- ❖ **Awareness and skills building:** Education related to sustainability and environmental issues to improve public awareness and build relevant skills.
- ❖ **Gender equality:** Solutions that promote the fair treatment of all genders, including female empowerment and considerations of gender equity.
- ❖ **Smart cities for sustainability:** Smart cities use modern digital technologies, such as apps for mobile phones, to engage and connect citizens in addressing their key sustainability challenges, such as city transportation, consumption patterns, energy, nutrition, water and waste.
- ❖ **Ecosystem restoration:** The process of assisting the recovery of an ecosystem that has been degraded, damaged or destroyed. Although this category would fit well under the agriculture, food, land and biodiversity cluster, it is considered as a separate category here due to the emphasis on this intervention in the reports. In future assessments, it could be adapted to refer to nature-based solutions, encapsulating those relevant innovations that draw on indigenous knowledge and ecological infrastructure.

**Figure 23.17: Seeds and proposals by cluster**

- ❖ **Effective governance:** Solutions to improve regional cooperation, and harmonization across scales, including to improve the management of interlinkages and tele-coupling between systems to reduce interregional inequalities.

Sixty out of the 157 workshop seeds, and seven out of the 34 Climate CoLab proposals, were coded against interventions exclusively from this new set of categories grouped as “other” (Figure 23.18). For seeds and proposals with measures that were coded across both “other” and at least one of the four clusters, some preliminary patterns emerged, although the sample sizes were small. For seeds, the most common cluster to be paired with “other” measures was energy, climate and air, with seeds linking this cluster to monitoring and reporting, smart cities, and awareness and skills building. Gender equality appeared in only two seeds and neither of these was coded against any of the four main clusters. In contrast, in the Climate CoLab proposals, gender equality, and awareness and skills building emerged as the strongest intervention categories and appeared in various proposals paired with all of the four main clusters. These proposals ranged in their suggestions from a mentoring network for women to female economic empowerment through activities like beekeeping. Agriculture, food, land and biodiversity emerged as the strongest cluster paired with various “other” interventions. While monitoring and reporting was a strongly represented measure in seeds, it was far less prevalent in Climate CoLab proposals.

Two interventions are highlighted in the platforms of bottom-up initiatives that are not included in the global assessment: sharing economies and circular economies. These show

**Figure 23.18: Count of the number of pairings of “other” measures with at least one intervention from a main cluster group**

| Workshop Seeds                        |                                          |                         |                       |                  | Climate CoLab                         |                                          |                         |                       |                  |
|---------------------------------------|------------------------------------------|-------------------------|-----------------------|------------------|---------------------------------------|------------------------------------------|-------------------------|-----------------------|------------------|

innovations that would boost the energy cluster, and also address production and consumption challenges in the agriculture, food, land and biodiversity cluster (see Box 23.6).

### 23.11.2 Implications for future assessments

The global review of the scenario provided a useful overview for synthesizing the range of potential interventions available for moving to a more sustainable future. Furthermore, by having concrete examples, it was possible to analyse the likely synergies and trade-offs between these interventions. However, the nine additional interventions that were uncovered in the bottom-up analysis should be considered in future global Outlooks (Figure 23.18). Smart cities, for example, were emphasized in the regional Outlooks as a means of achieving integrated responses to sustainability that capture many interventions towards transformative change. Exploring these urban opportunities, and the role they have in shifting urban-rural dynamics, should be a strong focus in global assessments given current population and urbanization trends. The bottom-up initiatives highlight sharing economies and circular economies as fast-evolving, and region-specific emerging interventions. Future global assessments should aim to factor the impact of such interventions into their outlook. Although the important role of indigenous and local knowledge in sustainability innovations not added in as a separate category, this has been captured as an important aspect in similar participatory processes undertaken by IPBES (See Lundquist 2017; IPBES 2018e) and could be highlighted in the next iteration of assessments.

Regional emphasis for the same intervention, or clusters of interventions, can differ enormously across and within regions.

Collecting, piloting and scaling a diverse range of bottom-up initiatives that are relevant to the local context can therefore be extremely useful in providing tangible examples to policymakers of otherwise generic pathways. Effective governance, and awareness and skills building were two interventions that all Regional Assessments emphasized. By comparing the interventions identified in the chapters presenting the Outlooks from the Regional Assessments with interventions identified from the review of the scenario literature, we identified several gaps, which should be noted and explicitly considered in future Regional Assessments. The most notable gaps were in the human well-being cluster, and in the inclusion of more social and behavioural interventions in the other clusters (e.g. nutrition management, diet change, energy access).

The review of the global scenario literature showed clearly that some interventions towards sustainable development could achieve synergies across multiple targets, while others may lead to trade-offs with specific targets. Table 22.1 provides a template for understanding which interventions trade off against each other or provide co-benefits. This systematic consideration of synergies and trade-offs between interventions would ensure an integrated approach that links top-down and bottom-up visioning.

### 23.12 Enabling conditions for transformations

The literature argues that transformations for sustainability require innovation – both technological and institutional (Olsson *et al.* 2017). Chapter 24 elaborates more fully on the relationship between policy and enabling transformative change towards achieving specific future goals. This chapter concludes with a discussion of what types of conditions are

#### Box 23.6: Case study: food systems

GEO-6 identifies the food system as a key cross-cutting issue due to its wide-ranging environmental impacts (water, land and GHG emissions) (see Chapters 4, 8 and 17). In the stakeholder engagement and crowdsourcing initiatives throughout the GEO-6 process, 27 out of the 156 workshop-collected seeds related directly to food, and 11 out of the 34 Climate CoLab finalists' proposals did as well. There was a willingness demonstrated by participants to embrace a more sustainable food system, with a large diversity of proposals including dietary change (e.g. eating less meat), reduction of waste in the food distribution system, and alternative production systems. Some workshop seed proposals did not address environmental impacts explicitly, such as those relating to food waste; however, given that an estimated one-third of food produced globally is wasted (see Chapter 8), reducing this would make more effective use of the natural resources consumed by agricultural production.

Several of the workshop seed proposals related to dietary change, specifically advocating increased uptake of – and support for – vegetarian and vegan diets. Such diets are widely understood to demand less land, water and energy than meat-based diets (Pimentel and Pimentel 2003), although regionally appropriate livestock rearing on pasture can be sustainable (Eisler *et al.* 2014). Others related to alternative farming methods (e.g. urban agriculture, rooftop farms, agroforestry) that could potentially have a positive impact on food security while reducing dependence on land and/or water resources. The Climate CoLab proposals contained more detail than the seed initiatives collected during the face-to-face stakeholder workshops. While the dominant focus of these proposals was obviously climate change, about one-third were related to the food system. Proposed solutions ranged from very broad-scope, global interventions such as a sustainability network involving “tens of thousands of food forests” through to more targeted interventions such as improving the moisture-retention capacity of agricultural soils in drought-affected parts of Africa. Notwithstanding the challenge of demonstrating effectiveness, the bottom-up scenarios show a clear willingness to embrace changes in the food system, suggesting a degree of public awareness of the necessary changes identified in the modelled pathways in Chapter 22.

Some of the proposed interventions, both from the seed workshops and from the Climate CoLab platform, could represent game-changers that – subject to further, rigorous examination – have the potential to fundamentally alter the way to develop model-based food-production scenarios in the future. The modelled links between population, meat consumption, average agricultural yields and resultant land use could be substantially reimagined in light of, for instance, widespread reuse of food waste for nutrient recovery (Cordell *et al.* 2011), combined with regenerative, ecological and multifunctional agriculture systems that have the potential to both increase and diversify yields (Horlings and Marsden 2011). In addition, radical models of optimized hypothetical diets have also been presented in the literature (Schramski *et al.* 2011; Ward *et al.* 2014), which could play a role in altering the conventional views in scenarios, of a rigid relationship between humans and land use.

required to enable bottom-up initiatives to scale and achieve potentially transformative change. There are many existing and ongoing initiatives that aim to achieve the SDGs and other global multilateral environmental agreements. Although these initiatives may be the potential building blocks of a more desirable future for people and the planet, higher-level enabling governance conditions will be crucial to their scalability (Moore, Riddell and Vocisano 2015).

A large amount of literature exists regarding sustainability transformations that provides a useful framework to understand the governance conditions needed to transform unsustainable systems and scale the innovations mentioned by workshop seeds and Climate CoLab proposals. Sustainability transformations are often broken down into multiple phases, with temporal periods related to a problematic status quo, a preparation phase in which innovations begin to develop, a navigation/acceleration phase in which innovations grow and become part of the new system, and an institutionalization phase in which a more desirable system is made sustainable in the long term (Olsson *et al.* 2006; Moore *et al.* 2014; Pereira *et al.* 2018a). For transformations to occur successfully, each of these phases requires governance conditions that are strongly

enabling. These enabling conditions can best be broken into supporting conditions for the scaling innovations appropriately and disrupting conditions for the weakening of existing, problematic structures.

To connect the theory to the bottom-up results, **Table 23.3** introduces the enabling and disruptive conditions for the transformations identified by the existing literature and provides examples that connect back to the workshop seeds and Climate CoLab proposals.

### 23.13 Key messages

The analysis of potential bottom-up and regional solutions for achieving a healthy planet, healthy people highlighted the need to do the following:

1. Integrate top-down and bottom-up approaches to developing scenarios.
2. Consider the full range of actors involved in achieving sustainability.
3. Recognize the need for distributive justice when setting expectations about where action should take place.

**Table 23.3: Summary of enabling and disruptive conditions for the appropriate scaling up, out and deep of potentially transformative innovations**

| ENABLING CONDITIONS                                                                                                                                                                                                                                                                                                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Establishing and supporting markets for innovations</b><br><i>Governance for transformations should involve establishing and supporting new markets for innovations. This consists of policies like regulations, tax exemptions, deployment subsidies and labelling</i>                                           | Some seeds and proposals mentioned creating and expanding markets such as an ethical fashion industry, and many others looked at innovations related to new and growing markets within the circular and sharing economies. These changes may require market-supporting policies like the labelling of fashion projects that meet certain standards, and subsidies that make niche innovations (e.g. in reusing waste) more affordable for consumers. More generally, policymakers and stakeholders should constantly explore how more sustainable markets related to identified innovations can be supported until they become the norm.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Supporting innovation experimentation and learning</b><br><i>Learning and experimentation support includes support for research and development, deployment and demonstration, policies that stimulate entrepreneurship, incubators, low-interest loans, venture capital and supportive regulatory conditions</i> | Not many seeds and proposals specifically addressed experimentation and learning support. The most relevant seed was an innovation lab focused on sustainable innovations at the local level. However, given that the seeds and proposals are new innovations predominantly in their prototype or early stages of development, support for innovation experimentation and learning is needed to ensure continued growth. Governance related to all seeds and proposals should strive for continuing improvements to make the solutions viable in the long term.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Financial resource mobilization</b><br><i>Financial resource support is the mobilization of financial capital through funding mechanisms, low-interest loans and venture capital</i>                                                                                                                              | A large number of seeds and Climate CoLab proposals identified a need for greater financial mobilization including the mobilization of domestic funds; the Inga Foundation's proposal seeks international funding to help fund its projects; Govardhan Ecovillage proposes a Green Innovations Fund; and "Framework for Community-based Sustainable Development" mentions a need for developed countries to transfer financial resources (and technological expertise) to less developed countries.<br><br>Related to supporting markets, supporting experimentation and learning, and financial resource mobilization is the emphasis on subsidies and incentives to support new innovations. Workshop pathways, particularly those developed in the Singapore workshop, emphasized the need for subsidies to promote renewable energy development, green urban infrastructure, and sustainable farming. Climate CoLab proposals went into further depth. The proposal "Climate protection by the elderly" called for incentives for the elderly to work, incentives for developing carbon sinks, and education subsidies for children involved in the programme. A proposal submitted by the Govardhan Ecovillage suggested subsidies for organic farmers. Another example, "Business plan for production and marketing of compost from urban solid wastes", suggests incentives and subsidies for individuals, cooperatives, businesses, etc. |

| Enabling/disruptive condition and description<br>(Adapted from Kivimaa and Kern 2016)                                                                                                                                             | Connection to the workshop seeds and Climate CoLab proposals                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Human resource mobilization</b><br><i>Human resource support is the mobilization of human capital through education and labour policies</i>                                                                                    | Human resource mobilization was a salient theme within the seeds and proposals, particularly the role of educating and engaging people on environmental issues. There was a large number of awareness, knowledge, and skills development solutions, all of which help to mobilize people towards transformations. Seeds-based visions from all four workshops also listed public awareness as a key component of realizing the participants' imagined sustainable futures. Some unique and exciting examples of human resource mobilization include educating the youth to work on climate issues through the 'Youth Climate Leaders' and 'Youth Informing Communities on Climate Change Adaptation through building homes' Climate CoLab proposals, and the many app-based solutions that make environmental engagement accessible. More broadly, for significant scaling up of solutions, labour policies will need to promote and reflect the same development priorities as the solutions. Considering that many seeds referred to the development of solar power, there will be a need for labour and training policies, for example, to help promote education and skills development to meet scaling up needs. |
| <b>DISRUPTIVE CONDITIONS</b>                                                                                                                                                                                                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Control policies</b><br><i>Control policies are taxes, trade restrictions and regulations that can be instituted by government actors to make existing processes less profitable or more sustainable</i>                       | Seeds and proposals related to control policies included introducing limits on plastic, cutting red meat from diets, and bans and taxes on plastic packaging. Control policies like taxes that internalise social and environmental costs and restrictions appeared less often in the bottom-up initiatives than many other enabling conditions as they are related to dealing with existing structures rather than innovating for new solutions. It is important to acknowledge that for all seeds and proposals, transformations usually have winners and losers (Meadowcroft 2011; Geels 2014). As such, for every new innovation there are displacements that can be promoted through control policies (and should be explored), although such policies should consider their wider implications as they can have unintended consequences.                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Rules reform</b><br><i>Rules reform consisting of radical policy reforms and changes in overarching rule structures</i>                                                                                                        | A few seeds and proposals suggested entirely new rule structures to promote sustainability, such as embracing the concept of a well-being economy. These included lowering the age of decision makers (e.g. to vote) and policymakers, introducing new financial systems that incorporate the value of the environment, and expanding the circular economy with extended producer responsibility.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Reduction in existing regime support</b><br><i>The removal of supporting conditions that have allowed for the existing, problematic structures to be successful</i>                                                            | Solutions that tackled the conditions that make existing systems successful mostly focused on informing and engaging people on why the existing structures are problematic and how to do things differently. For example, many apps looked at teaching users how their lifestyle was environmentally unfriendly and how to improve, and programmes such as 'No Straw Tuesdays' aimed to challenge the excessive use of straws and plastics more broadly. This can be extended to include the removal of environmentally and socially perverse subsidies.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Changes in networks and key actors</b><br><i>The replacement of incumbent actors and the breaking of powerful actor-network structures in favour of new actors and networks more favourable to the desired transformations</i> | Several workshop pathways and Climate CoLab finalists referenced changing current actor relations, specifically through building collaborative environments and new, involved networks of stakeholders. Decentralized power and action in large networks was a key component of many seeds. One Climate CoLab proposal, 'C'SQUARE' reflected the trend found in workshop pathways and mentioned the need to empower and mobilize citizens in order to gather their opinions to improve urban areas. Its success was dependent on strong partners and collaborations. The 'Organic Monetary Fund' and "Framework for Community based Sustainable Development" Climate CoLab proposals focused on engaging stakeholders at all levels, including the national governments, international organizations, local communities and relevant experts.                                                                                                                                                                                                                                                                                                                                                                         |

Ongoing efforts to incorporate the impact of bottom-up climate action into existing climate scenarios illustrate how including bottom-up activities can do the following.

- ❖ Create a more accurate understanding of existing sustainability pathways and where there are gaps.
- ❖ Help national governments to support and account for bottom-up activities in their own agenda setting.
- ❖ Identify small-scale initiatives that could provide functions (e.g. capacity-building, piloting of innovative solutions) that may be difficult to quantify but can be critical to achieving the transition to a low-carbon society (Chan, Brandt and Bauer 2016). The concentration of Climate CoLab

proposals in the global South suggests that these activities could, for instance, fill a key data gap in current records of sustainability innovations beyond the global North.

### 23.13.1 Methodological learnings

This lack of bottom-up futures in the context of sustainability poses major challenges. In terms of legitimacy, large-scale global or regional futures that do not represent the diversity of many different lived experiences, world views and discourses risks giving insufficient space for the concerns and needs of different societal actors. It is difficult to imagine transformative change if large-scale sustainability futures do not draw on

insights and perspectives from local and national levels, as well as incorporating diverse knowledge systems like those of indigenous people. Many of the seeds for better futures exist today in the margins of current systems, which often means that they operate locally, even if they are sometimes organized through trans-local networks (Bennett *et al.* 2016). This trend goes for seeds that may contribute to more desirable futures, such as practices, technologies and forms of governance that might have a global impact. It also holds for new threats and risks that might modify the challenges of the Anthropocene as they emerge, such as conflicts, natural resource crises, diseases and problematic technologies (Steffen *et al.* 2015). Furthermore, the lack of bottom-up contributions to global sustainability futures also has consequences for how these scenarios and visions are used. If global futures lack connections to on-the-ground realities, they may be deemed too theoretical and too generic to inform decision-making. If such futures are used, the top-down framing of future challenges at local levels can limit what gets considered and affect the legitimacy of who contributes to this framing of the future (Vervoort *et al.* 2014).

The top-down scenarios based on integrated assessment models, and the participant-based bottom-up initiatives both have strengths and weaknesses as tools to chart a course towards sustainability. If used well, both approaches have the potential to complement and mutually reinforce one another, as shown in **Figure 23.19**.

The seeds workshops and Climate CoLab proposals represent a small sample, but they show that some solutions are highly synergistic in terms of the SDGs addressed, extremely diverse in scope, and multidimensional in ways that make categorization by any single dimension challenging. The initiatives targeted all SDGs, but were most focused mainly on SDGs 2, 3, 11, 12 and 13. The domains addressed by the initiatives were diverse, and – beyond the expected focus on climate change by Climate CoLab proposals – both the seeds and the Climate CoLab proposals focused in a cross-sectoral manner on the food, energy, water, and waste sectors and their interconnections. Seeds and Climate CoLab proposals envisioned changing systems largely through new technologies, but they also envisioned change occurring through lifestyle shifts, enabled by improving environmental awareness through education,

skills development and knowledge generation. Climate CoLab proposals differed slightly and looked at changes in production practices and proposed new organizations and businesses as well as proposing the development of awareness, knowledge and skills. Finally, in examining the Climate CoLab proposals, an overwhelming focus was put on solutions for the global South, particularly for countries in Africa and Asia.

At the same time as quantitative, top-down approaches can be used to inform and strengthen the physical basis for bottom-up initiatives, those bottom-up ideas can in turn challenge overly rigid or outdated assumptions in top-down models. Using bottom-up approaches, it can be possible to identify game-changing concepts that fundamentally restructure the way we view future scenarios. One tangible example is the development of small-scale, decentralized renewable energy systems. The rapid pace of technological development and the associated decrease in the cost of, among others, solar photovoltaics and battery storage, coupled with ICT, makes microgrids a new possibility for areas not yet served by conventional electricity from fossil fuels. This has already become a reality in Kenya since the establishment of M-KOPA, a mobile-enabled payment system for Solar Home Systems in 2013. These technologies – and the public demand to embrace them – mean that the types of energy transition characterizing the past (coal to oil, oil to gas, gas to large-scale renewables) may not necessarily characterize the leapfrog development of energy supplies in the future.

There are many similarities between the macro-level pathways in Chapter 22 and the bottom-up interventions in this chapter. Interventions discussed in both have significant co-benefits for several SDGs. There is a prominent focus on urban sustainability and on food waste and diet change in both analyses (**see Boxes 23.5 and 23.6**). A crucial complementarity that becomes clear is that the macro-level pathways in the global models allow for an integrative analysis of many contextual drivers and interventions, while the bottom-up pathways provide information about the theories of change underlying the ways of scaling of high-potential practices to achieve the SDGs. The complementary insights provided by the bottom-up and the macro-level pathway analyses demonstrate that further integration of these approaches has much potential. For instance, global modelling results could be used

**Figure 23.19: Conceptual framework for mutually beneficial feedbacks between top-down and bottom-up approaches to generating sustainable scenarios**

to provide direct global contexts for stakeholders developing bottom-up pathways; and bottom-up pathways can provide directions for future model extensions.

The platforms pioneered in GEO-6 represent an opportunity – if adopted in future assessments – for the top-down scenario-development community to receive feedback on the public acceptance of the various interventions and their trade-offs adopted. To meet the requirement of an increased food supply, for example, pathways include the expansion of agricultural land for rain-fed agriculture (at the expense of biodiversity), or increased use of fertilizer and irrigation to improve yields on the land already in use (at the expense of water resources and pollution). Stakeholders could be consulted to gain insights into the relative acceptance of different options, as well as to identify blind spots in the modelling approach that may mean alternative, synergistic solutions are being overlooked. Similarly, gaps in actual interventions that could help to achieve SDG targets can also be revealed – as is the case with interventions specifically aimed at drivers like population growth that present an important challenge to sustainability, as identified in Chapter 22 and across the chapters of Part A.

Longer-term possibilities for integration could include quantitative aggregation of local scenarios and seed initiatives with direct links to model inputs and outputs; and model integration with online crowdsourcing of bottom-up pathway elements.

### **23.14 Key interventions and a critical need to recognize distributive justice given global inequities and inequality**

The analysis of the Climate CoLab proposals, where an overwhelming focus was put on solutions for the global South, particularly countries in Africa and Asia, highlights existing inequities in the perceptions of where interventions are necessary for transformation, and of who needs to act. While our analysis was of a small subset of studies, if it is indicative of broader perceptions, the burden placed on the global South to transform and implement development initiatives or solutions exacerbates current power inequities in global governance structures (Nagendra 2018; Newell 2005; Parks and Roberts 2008; United Nations Research Institute for Social Development [UNRISD] 2016). This imbalance can obscure or ignore the role of the global North in current development trajectories (e.g. focusing only on poverty alleviation and not discussing wealth redistribution). While the GEO Regional Assessment for Europe did highlight trade-offs and tensions associated with tele-coupling, the limited emphasis on tele-couplings generally is of concern and requires concerted effort (tele-couplings highlight consumption patterns in one region driving environmental concerns related to production in another region) (Liu *et al.* 2013; Seaquist, Johansson and Nicholas 2014). Here, incorporating principles of distributive justice – normative principles designed to guide the allocation of the benefits and burdens of economic activity based on fair distribution (Lamont and Favor 2008) – can help to construct a development agenda based on principles of equity and equality. Such an equality-based and equity-focussed framework can

help to account for the disparate developmental conditions of the global South and global North (Rosales 2008; Pelletier 2010; Nagendra *et al.* 2018). This process can provide more equitable options for where and how to implement the solutions with the most transformative potential to achieve sustainable development; for example, in reforming consumption and production patterns or in instituting market mechanisms such as caps in emission-trading schemes, carbon taxes and offsetting schemes. Addressing these global inequities is a means through which to achieve the global goal of equality.

Many of the solutions presented in this chapter do offer the opportunity for developing countries to leapfrog onto more sustainable and equitable development trajectories. The use of ICT plays a major role in driving change in the bottom-up pathways – a result of a stronger focus on theories of change and on *how* change processes are facilitated. There are already many good examples of how this is being leveraged for change in the global South (Karpouzoglou, Pereira and Doshi 2017; Ockwell *et al.* 2018). The roles of different societal actors and diverse knowledge systems are made explicit in bottom-up pathways. There is an important role, for instance, for city-level government actors in many proposals. The proposals also include a role for global networks of, for instance, sustainable cities or energy cooperatives. Similarly, diverse higher-level enabling conditions like international agreements, again tied to specific actors, are discussed as part of the bottom-up pathways and their seed initiatives (see Byrne *et al.* 2018 for a discussion on the need for international agreements to enable niches for achieving global energy and climate ambitions).

Chapter 22 identifies trade-offs in the balance between yield improvements and a set of human and environmental goals that include preventing nutrient pollution, limiting climate change, improving child health, providing universal access to clean water and sanitation, and neutralizing land degradation. The present chapter has offered some potential solutions for minimizing such trade-offs and maximizing the synergies. There was a large emphasis on food systems being a critical intervention point for moving towards a healthier planet as well as healthier people. Many seeds and proposals addressed current challenges in the food system by referencing examples that are taking place right now – examples of urban agriculture, aquaculture, diet-change initiatives, and indigenous and local knowledge exchanges (see Annex 23-1).

Chapter 22 also identified a challenge in promoting economic development while reducing emissions. The many initiatives for sharing and circular economies seen in the bottom-up pathways help towards a transformative shift to a well-being economy that no longer presents trade-offs. These pathways offer grounded methods to address global trade-offs.

This analysis has highlighted the specific interventions that governments could facilitate in the shift towards a healthier planet with healthier people, and has highlighted how these interventions differ across different locations. It has also offered some specific examples of where and how change is starting to happen. These are further developed in Chapter 24.

# Chapter 24

## The Way Forward

**Coordinating Lead Authors:** Mikiko Kainuma (Institute for Global Environmental Strategies [IGES]), Diana Mangalagu (University of Oxford and Neoma Business School), Ghassem R. Asrar (Pacific Northwest National Laboratory (PNNL), Klaus Jacob (Freie Universität Berlin)

**Lead Authors:** Laura Pereira (Centre for Complex Systems in Transition, Stellenbosch University), Alexis Rocamora (Institute for Global Environmental Strategies), Detlef van Vuuren (PBL Netherlands Environmental Assessment Agency), Fintan Hurley (Institute of Occupational Medicine), Steve Hedden (Frederick S. Pardee Center for International Futures, University of Denver), Paul Lucas (PBL Netherlands Environmental Assessment Agency), Peter King (Institute for Global Environmental Strategies)

**Contributing Authors:** Kei Gomi (National Institute for Environmental Studies [NIES]), Robyn Lucas (National Centre for Epidemiology and Population Health, The Australian National University)

**GEO Fellow:** Mandy Angèl van den Ende (Utrecht University)

## Executive summary

**Systemic and transformative policies, technologies and social practices, if used together and holistically, have the potential for achieving the Sustainable Development Goals (SDGs) and other Multilateral Environmental Agreements (MEAs)** (*established but incomplete*). Transformation is a

disruptive process that goes beyond the mere incremental improvement of existing technologies and practices to serve human needs, in an innovative manner. Its origin could be technology, policy or social norms and practices, but to be transformative it should be all encompassing (i.e. holistic). Transformations do not necessarily result from top-down approaches. They emerge from the co-evolution of multiple interdependent factors and the active engagement of diverse stakeholders. {24.2}

**Transformative pathways to sustainable development require (1) visions to guide systemic innovation towards sustainability, (2) social and policy innovation, (3) the phasing out of unsustainable practices, (4) policy experimentation and, (5) engaging and enabling actors and stakeholders** (*established but incomplete*). Innovative solutions are required to link policies to SDGs, to promote viable business models, to finance the support and management of investment risks, to support international cooperation, and to address the concerns of citizens and stakeholders and ensure their active participation in the entire process. {24.3}

**The promotion of systemic innovation is key to socioeconomic development** (*established but incomplete*). Many countries are struggling to develop, adopt and diffuse innovative technologies due to the perceived high costs associated with them and, in some cases, technical or regulatory barriers to implementation. For example, in some countries, low-carbon technologies have been adopted by industries only to the extent that they have been successful in market competition. However, the development of policies and governance – including financial mechanisms, policy innovation and the relevant human capacities – at local, subnational and national levels to create an enabling environment, is crucial for wide-scale diffusion. {24.3.1}

**Transformative environmental policies have the potential to complement existing ones** (*established but incomplete*).

The potential of the environmental policies developed and implemented over the past decades is far from realized. Some strategically important environmental policies that address technologies, reduce emissions and improve resource use efficiency lack effective implementation. For example, sectoral policies often lack a consideration of environmental concerns. Transformative policies do have considerable potential to go beyond these measures, but it is less certain that experimental and systemic innovation will succeed in the short term. Accordingly, both approaches, with a focus on more effective implementation of strategically important existing and transformative policies, should be pursued together. {24.1, 24.4}

**A healthy planet is the ultimate foundation for supporting all life forms and human well-being, which depend on the viability of Earth's life-support system** (*well established*). The

Healthy Planet, Healthy People perspective recognizes that human activities have transformed Earth's natural systems and disrupted its self-regulatory mechanisms and life-support system. Economic growth has come at the cost of ecosystem health. The resulting environmental degradation has increased the burden of disease through exposure to harmful pollutants as well as through reduced access to the ecosystem services that we enjoy (e.g. clean air, biodiverse ecosystems, healthy food, clean oceans, land and freshwater). The Healthy Planet, Healthy People approach will be central to global efforts to promote the stewardship of resources from air, biodiversity, land, oceans and freshwater to support human well-being, and the sustainability of the Earth system. For example, the global health savings from reduced air pollution are estimated to be 1.4-2.5 times greater than the costs of mitigating climate change. The proposed strategy to reach the less than 2°C warming target by the end of this century is projected to have the highest benefit-to-cost ratio – where the global health savings (US\$54.1 trillion) are estimated to be more than double the global policy costs (US\$22.1 trillion). {24.4}

## 24.1 Approaches for environmental policy: strategic and transformative

The 2030 Agenda for Sustainable Development, together with a range of Multilateral Environmental Agreements (MEAs), set an ambitious long-term vision for the universal pursuit of sustainable development through economic, social, environmental and institutional transformation (Chapter 20). Although progress has been made in managing some environmental problems (e.g. ozone depletion, acid rain), overall global agreements and associated policies have not been able to bend the unsustainable trajectory. Without new policies and effective actions, the ambitious sustainable development vision will not be met (Chapter 21).

Options for bending the prevailing trends do exist. Moving to a sustainable path requires a mix of technological innovations, lifestyle changes and local, regional, global and decentralized solutions with stakeholder engagement, at an unprecedented pace of change (Chapters 22 and 23). The potential from efficiency improvements and emission reductions are far from fully exploited, yet because of rebound and growth effects, it is questionable that they will be sufficient. More disruptive and transformative changes, including new social practices, seem necessary. This chapter discusses promising innovative approaches and transformative, effective policies that will help to attain the goal of a Healthy Planet, Healthy People.

Part A of this report provides the evidence that the current pace of change is inadequate to reverse the environmental harm we are already experiencing. Without a fundamental redirection, most environmental domains will continue to degrade, threatening the economic and social progress achieved to date and the fate of the multiple species that share planet Earth. Part B concludes that, despite a proliferation of policy innovation, often only second-best and small-scale solutions are being observed, rarely going beyond technological fixes. Moreover, potentially effective and ambitious environmental policies are not getting traction. The future projections and potential pathways in Part C suggest that new policies and measurable actions are required at all levels (i.e. local, national, regional and global) to attain the Sustainable Development

Goals (SDGs) and targets by 2030, and beyond. The analysis shows that for most environmental goals, the projected conditions appear to worsen, e.g.,

- ❖ More and more people will be living in water-stressed areas (Hejazi *et al.* 2014).
- ❖ Increasing greenhouse gas emissions will result in a large overshoot of the “well-below-2°C” target of the Paris Agreement on climate change (Iyer *et al.* 2015; United Nations Framework Convention on Climate Change [UNFCCC] 2015).
- ❖ The rapid decline in biodiversity will continue (Intergovernmental Science-Policy Platform on Biodiversity and Ecosystem Services [IPBES] 2018).
- ❖ Stressed food systems will continue to result in persistent malnourishment, affecting both human well-being and planetary health (Whitmee *et al.* 2015).

Some pathways for change are assessed in various sustainability scenarios in Chapter 22, and through the potential seeds of change in Chapter 23. The sustainability challenge, however, requires new strategies that will stretch humanity's collective imagination, and the current knowledge and action. Incremental steps are insufficient.

**Figure 24.1** illustrates the sustainability trajectories for integrated and transformative approaches compared with business as usual. Business as usual, with unambitious environmental policies, lacks effective implementation and holistic integration in other sectoral policies and therefore will not contribute to safeguarding the environment and meeting the sustainable development goals. Stronger environmental policies, including those that provide economic incentives for reducing emissions and improving the efficiency of resource use, do have considerable potential. A transformative approach, based on experimentation and consideration of social practices may be more open-ended and less certain in its direction and chance of success, but it offers greater potential for higher impact and achieving sustainability goals. Both policy approaches could be pursued in parallel to ensure a greater chance of success in both the short and long term.

**Figure 24.1: Different policy approaches**

## 24.2 Transformative change

Our needs for nutrition, health, energy, housing mobility, and so on, are met by a range of social-ecological, socio-technical and socioeconomic systems (Folke *et al.* 2011; Geels and Schot 2017; Díaz *et al.* 2018). Such systems provide their services to society not only by a single technology or service, but are embedded in infrastructure, markets, institutions and social practices, including norms and values (Grießhammer and Brohmann 2015). The different elements of these systems mutually reinforce and stabilize each other, but they are viewed relatively independently of each other, making it difficult for environmental policies to fundamentally change the structure of the systems and organizations involved, let alone their interlinkages and interactions.

Environmental policies have triggered innovation in many sectors through strategies and actions such as ecological modernization, green economy, the valuation of ecosystem services, and the potential for further innovation remains considerable. There is significant potential for improving resource productivity by factors of four to ten (i.e. with one unit of resource, four to ten times more goods are produced) (Schmidt-Bleek 2008; von Weizsäcker *et al.* 2009). Improved resource productivity is necessary but not sufficient because it does not change the underlying systems adequately to achieve the required transformation towards a sustainable society. Therefore, a fundamental reconfiguration of societal systems, including mental models and thought processes, institutions, and norms and values, is necessary (Westley *et al.* 2013; Olsson, Galaz and Boonstra 2014; Bennett *et al.* 2016). Such transformations do not necessarily result from top-down approaches. They emerge from the co-evolution of multiple interdependent factors and the active engagement of diverse stakeholders (Chapter 23). It is important to coordinate actors and resources, guided by a vision of a dramatically different future.

Fostering the ability to transform could enable new development trajectories for social-ecological systems that are more sustainable and have more space for dynamic innovation (Folke *et al.* 2010; Jacob *et al.* 2018). Transformations start from niches defined as small, protected spaces in which new practices can develop, thus causing changes from local to regional and global scales (Loorbach and Raak 2006; Olsson *et al.* 2006; Jänicke and Rennings 2011; Olsson, Galaz and Boonstra 2014). Once feedback mechanisms have reached a critical mass, however, transformative change can be abrupt, and existing technologies and their supporting infrastructure, knowledge, capital and institutions are de-legitimized, and the transformative change is ultimately well integrated into norms and practices (Arthur 2011).

Historical transformation has followed this pattern, starting from innovation in niches, and challenging prevailing practices, with a co-evolutionary and emergent character (Diamond 1997; Arthur 2011; Westley, McGowan and Tjörnbo eds. 2017). In many cases, these transformations were unguided processes that led to increased resource use, emissions and environmental degradation rather than the sustainable use and stewardship of resources and the environment. Hence, there is a need to navigate and guide transformations onto more desirable trajectories (Olsson *et al.* 2006; Jacob *et al.* 2018).

Transformative approaches may differ country by country. Moreover, while current policies have been insufficient to address environmental problems, they need to continue in terms of pollution control, efficiency improvements, planning for the environment and so on. Some countries could achieve transformative changes by leapfrogging to best practices, whereas others may need incremental changes in their policies and practices before reaching transformative stages. Deploying instruments such as economic incentives for innovation and changes in existing economic frameworks, including internalization of external costs, eliminating environmental subsidies, promoting the valuation of ecosystem services, reforming green budget investments, could all play key roles in bringing about transformative changes.

There is no simple recipe for enabling transformative change towards sustainability, but recent methodological innovations emphasize the need for different actors to come together and to experiment with innovations that have the potential for systemic transformation (Frantzeskaki, Wittmayer and Loorbach 2014; Pereira *et al.* 2015). Many of these processes are dubbed lab-based processes. The features of these real-world labs that contribute to transformation include experimental methods, a transdisciplinary mode of research, and the scalability and transferability of results as well as scientific and societal learning and reflexivity (Schapke *et al.* 2018). Examples include social-innovation labs (Westley *et al.* 2012), resilience labs (Frantzeskaki *et al.* 2018), transformation labs (Charli-Joseph *et al.* 2018; Zgambo 2018; van Zwanenberg *et al.* 2018), living labs (Budweg *et al.* 2011; Hooli *et al.* 2016), including urban living labs (Cosgrave *et al.* 2013; Voytenko *et al.* 2016) and transition arenas (Loorbach 2010). Other related processes draw on fields such as foresight – an approach that covers a wide range of methods to systematically investigate the future across systems like the food system (Hebinck *et al.* 2018), urban systems (Potjer, Hajer and Pelzer 2018) or energy systems (Hajer and Pelzer 2018). Some processes refer to new ways of thinking about how change needs to happen, from the individual level through ideas like “inscaping”, where individuals surface their inner experiences (Nilsson and Paddock 2014), to how groups can undergo change using concepts like “Theory U” (Scharmer 2007), and drawing more on stories and lived experiences to create real connections with people and their environments in the future (Galafassi *et al.* 2018). These system interventions have been defined as transformative spaces, safe collaborative environments in which experimentation with new configurations of social-ecological systems, crucial for transformation, can occur (see Charli-Joseph *et al.* 2018; Drimie *et al.* 2018; Dye 2018; Galafassi *et al.* 2018; Hebinck *et al.* 2018; Marshall *et al.* 2018; Moore *et al.* 2018; Pereira *et al.* 2018; van Zwanenberg *et al.* 2018). These approaches can be an important step in navigating onto a more sustainable trajectory.

## 24.3 Building blocks for transformation

Five key approaches to guide, shape and enable transformation can be identified:

- i. visions to guide systemic innovation towards sustainability;
- ii. social and policy innovation;
- iii. the phasing out of unsustainable practices;
- iv. policy experimentation; and
- v. engaging and enabling actors and stakeholders.

These necessary ingredients are discussed and illustrated through the examples given in the sections that follow.

### 24.3.1 Visions to guide systemic innovation towards sustainability

An increasing number of governments, cities, companies and communities are expressing compelling visions of a more sustainable future and sharing their strategies and plans for achieving those visions. Many of these visions realize that new ways of measuring progress are also needed (Midgley and Lindhult 2017).

The concept of gross national happiness (GNH) as an alternative to monetary values to measure societal progress was introduced in Bhutan's 1999 strategy for sustainable development (Niestroy, Schmidt and Esche 2013; Jacob, Kannen and Niestroy 2014). Since then it has been evolved as the core vision for Bhutan's governmental and economic activities. Policies and investments are assessed against their contribution to increased GNH instead of their monetary cost and benefits. GNH is key for Bhutan's five-year plans and is included in its Constitution. A GNH commission monitors the implementation. GNH is based on four pillars:

- i. equitable socioeconomic development (equity between individuals, communities and regions to provide social harmony and stability);
- ii. conservation of the environment;
- iii. preservation and promotion of culture (appreciation of the country's cultural heritage and the preservation of spiritual and emotional values); and
- iv. promotion of good governance (developing institutions and human resources and providing opportunities for participation).

In response to a regrettable history of deforestation and environmental degradation (Food and Agriculture Organization of the United Nations 2016), Costa Rica has developed a vision of modernity that gives environmental quality a prime place (Silva 2002; Johnson 2016). The 1994 Constitution of Costa Rica provides for "the right to a healthy and ecologically balanced environment" (United Nations, General Assembly 2014). Some recent policy approaches to attaining that vision include payment for ecosystem services, forest preservation for carbon credits, forest credit certificates, legal protection and preservation of iconic species, a ban on open pit mining and, most recently, a pledge to become carbon neutral by 2021. Although challenges remain in relation to water quality and marine protection, significant environmental improvements have stemmed from this overarching vision. For example, forest cover has improved from 26 per cent in the 1980s to 52 per cent in 2010 (United Nations, General Assembly 2014).

An increasing number of cities, communities and regions worldwide aim to reduce their carbon footprint and aspire to become zero-emission or carbon-neutral places (Yamanoshita and Aamano 2012). A clear definition for the scope of emissions (e.g. internal emissions based on the geographic boundary, or external emissions directly caused by municipal activities) addressed by such labels at the city level is under development worldwide (Kennedy and Sgouridis 2011; Straatman *et al.* 2018). Globally, 19 cities have committed to making net-zero-carbon buildings and infrastructure a central

piece of their investment strategy by 2030, and to revisit their current planning policies and regulations for existing buildings infrastructure to make them net-zero carbon by 2050 (C40 Cities 2018). Zero-emission city prototypes have been attempted by using renewable energy, cutting-edge technology, innovative urban planning and an emphasis on total reuse (Premalatha *et al.* 2013). Other initiatives focus on helping existing cities to get on a pathway towards net-zero emissions (e.g. World Business Council for Sustainable Development 2017) in which municipalities work together with businesses to jointly reduce CO<sub>2</sub> emissions, while focusing on sustainability priorities (Zadek 2004; Moore, Riddell and Vocisano 2015).

ProjectZero (2016) in the Sønderborg region (77,000 inhabitants) in the south of the Kingdom of Denmark has the declared vision of becoming CO<sub>2</sub>-neutral by 2029, based on sustainable growth resulting in new green jobs. This vision is being implemented by a public-private partnership involving the municipality and major businesses in the region. A milestone of a 25 per cent reduction in CO<sub>2</sub> emissions in 2015 was exceeded (at 35 per cent) (World Future Council 2016). Technological initiatives are taking place in cities and regions worldwide, such as expanded district heating networks, the conversion of supplies to CO<sub>2</sub>-neutral sources and the installation of onshore wind turbines and photovoltaic facilities, coupled with programmes that involve citizens and industries, such as the ZEROhousing and ZEROcompany programmes (Bulkeley and Betsill 2005; Betsill and Bulkeley 2006; Frantzeskaki, Wittmayer and Loorbach 2014; Fujino and Asakawa 2017; City of Melbourne 2018).

Iskandar Regional Development Authority (IRDA), a Malaysian federal government agency overseeing the country's economic and physical development, formulated a vision known as the Low-carbon Society Blueprint 2025. IRDA developed the Green Economy Guideline Manual as a means to implement this vision with the active participation of the business operators in the region, where there is significant domestic and foreign investment (Ho *et al.* 2013; Iskandar Regional Development Authority [IRDA] 2014).

### 24.3.2 Social and policy innovation

There is no single blueprint for the achievement of these visions, as they are all socially and ecologically embedded in national and local contexts, historical developments, cultural norms and values, and so on. Accordingly, transformation encourages massive social and policy innovation with no guarantees about which forms will ultimately prove successful and worthy of emulation in other domains. One emerging approach that is finding multiple applications is the concept of the sharing economy (e.g. shared accommodation and mobility systems), helping to move societies away from wasteful consumption of both renewable and non-renewable resources (see Section 23.3; Frenken 2017). Sharing accommodation and mobility to reduce environmental impacts is potentially transformative. Private vehicle ownership and solo use, with the high running costs of insurance, parking, maintenance, fuel, and so on, may be reduced by as much as 80 per cent within a decade if sound regulations and incentive schemes are implemented (Arbib and Seba 2017). Trust is no longer based on personal ties but on mechanisms such as peer ratings, business and liability regulations and third-party verification (Lan *et al.* 2017).

Some cities are contemplating making all public transport free. In some cities of Switzerland, for example, hotels provide guests with free passes to use public transport and avoid the traffic and parking congestion. Since 2013, permanent residents of Tallinn, the capital of the Republic of Estonia, have been entitled to use public transport after registration and the purchase of a green card for just two euros, after which all transport is free of charge. The motivations to introduce the scheme were:

- i. to promote a modal shift from private cars to public transport;
- ii. to improve accessibility for people on low incomes; and
- iii. to stimulate the registration of Tallinn residents and so increase the returns from income taxes (Cats, Susilo and Reimal 2017).

As more and more people gravitate to cities, the urban footprint on the hinterland becomes increasingly detrimental to the environment. One promising policy approach to minimizing these impacts, addressing climate change and strengthening community bonds is to create the necessary enabling conditions for increased urban agriculture – green rooftops, vertical farms and community gardens, for example. Of course, for many developing countries, urban agriculture has been a way of life (Orsini *et al.* 2013) with 11 per cent (Indonesia) to almost 70 per cent (Viet Nam and Nicaragua) of urban households earning income from urban agriculture. What has changed has been the increasing sophistication of urban agriculture, such as vertical farming (Association of Vertical Farming 2018) and green rooftops (City of Melbourne 2018), predominantly in more developed countries.

Promoting a circular economy is another potential opportunity for reducing CO<sub>2</sub> emissions and other waste and preserving natural resources and ecosystems (see Chapter 17). This concept is captured in the approach to managing the consumption of natural resources and to addressing related environmental and socioeconomic challenges that has been taken by the European Commission Circular Economy Action Plan, published in December 2015 (Wilts 2017; European Commission 2018). If materials are preserved in high-quality products or recycled and used as high-quality secondary raw materials, the circular economy can reduce industries' demands for primary raw materials (Wilts 2017). The concept of circular economy also promotes a decentralized approach to sharing, to providing services and to businesses' dematerializing innovations. For example, a decentralized mode of service provision, which is not necessarily dependent on product and material ownership, is rapidly becoming possible through the development of information and communication technologies and new business models (Kishita *et al.* 2018).

#### 24.3.3 The phasing out of unsustainable practices

A commitment to changing the current, unsustainable socioeconomic and environmental trajectory offers great opportunities in all aspects of daily life, with a high potential to generate the required transformations. The banning of single-use plastics provides one of the most recent examples, where the initial phase-out of lightweight plastic bags has moved into a much broader policy response at all levels, addressing the use of all kinds plastics (Onyanga-Omara 2013; European Commission 2018; United Nations Environment

Programme [UNEP] 2018). Developing countries are leading this transformation. In 2002, the People's Republic of Bangladesh became the first country in the world to completely ban thin plastic bags after it realized that around 80 per cent of the waterlogging in cities during floods was being caused by polyethylene bags blocking drains and increasing standing water. This also produced a breeding ground for mosquitoes, increasing the incidence of diseases such as dengue and malaria. Several other countries joined with similar initiatives, including the State of Eritrea in 2005 and the Republic of Kenya in 2017 (Njugunah 2017). Scaling out from tackling plastic bags, the European Commission (2018) made the ground-breaking announcement of banning around ten single-use plastic items (e.g. cutlery, straws, cotton buds, plates, coffee cups and stirrers) that account for 70 per cent of garbage in regional waters and beaches. This example was immediately followed by India, marking a historic breakthrough.

In some circumstances, natural materials may provide alternatives to plastics. For example, the Republics of Indonesia, India, Philippines and Kenya are using water hyacinth, which is among the most effective plants for removing carbon dioxide from the atmosphere, as a source of hard-wearing fibre or to produce paper and paper products, with the potential to reduce the demand for conventional plastic products. UN Environment is leading the information-sharing and education process at a global level through its Clean Seas campaign and, most recently, by making the theme for World Environment Day 2018 to beat plastic pollution (Dris *et al.* 2015; Ocean Care 2017). The policies to replace plastics with alternative materials will fail, however, to reduce marine debris if the disposal of the new alternative materials is not considered prior to their introduction. Better collection, recycling and waste management will help to reduce debris on land and in the ocean (Trucost 2016).

#### 24.3.4 Policy experimentation

Transformative policy can often be judged as successful only with the benefit of hindsight and careful monitoring and evaluation. Policy mistakes directly introduced at a national level may have long-lasting implications, such as some of the regrettable policies in the past for controlling population growth (Zhang 2017). Accordingly, the precautionary principle suggests that policy experimentation at smaller scales, combined with national support and continuous evaluation, may be a more sensible choice (Heilman 2008; Husain 2017; Shin 2018).

Policy experimentation at a local scale followed by scaling up is a hallmark of China's policy success (Heilmann 2008). This approach of deliberate experimentalism dates back to early land reforms and addressing agricultural production in the 1940s (Husain 2017). Local-scale policy experiments provide a space for tailoring and innovating policies that are closely monitored; if successful, they are subsequently scaled up, or if unsuccessful, halted. Shin (2018) refers to this approach as experimentation under hierarchy, complemented by performance incentives for local officials.

Experimental governance differs from traditional governance in that it emphasizes learning processes based on public-private partnerships. Experimentation is goal-oriented and seeks to overcome gaps between top-down policies and the challenges

at a grass-roots level (Antikainen, Alhola and Jaaskelainen 2017). These types of policy experiments have been practised for climate adaptation in the Kingdom of the Netherlands (McFagen and Huitema 2018). Climate adaptation experiments have also been practised in cities in developing countries, where experiments rely on community-based strategies that involve concerned community members and professionals, and that gain support from external agents. These adaptation experiments need to be in coherence with their urban political economic contexts to ensure transformative change (Broto and Bulkeley 2013; Chu 2016). Policy experimentation works well when the processes are more iterative and more participatory, reflecting both a long-term goal formulation and interactive strategy (Hilden, Jordan and Huitema 2017).

### 24.3.5 Engaging and enabling actors and stakeholders

Transformation, by definition, will change existing social-economic systems and create winners and losers. Such changes should not be feared, as the continuation of business as usual involves even greater disruption and larger numbers of losers. While it is not possible here to describe all the actors who need to thrive in the context of these emerging visions of sustainable development, many new opportunities will be created and need to be supported. Participatory approaches to engaging decision makers and actors in all phases of transformative change ensure greater acceptance and significantly reduce the time to adoption and produce greater ownership of such changes (Mitchell, Agle and Wood 1997; Umaemiya, Rametsteiner and Kraxner 2010; Smith, Ansett and Erez 2011; Asrar, Ryabinin and Detemmerman 2012; Asrar, Hurrell and Busalacchi 2013; IRDA 2014; Vallentin 2016). Such approaches are widely recognized in a number of international agreements stemming from Principle 10 of the Rio Declaration (United Nations Educational, Scientific and Cultural Organization 1992): “Environmental issues are best handled with the participation of all concerned citizens” (e.g. the Aarhus Convention, Escazu Convention, Talanoa Dialogue).

Innovative finance represents a key breakthrough in the complex pathway to achieving the SDGs. Business as usual does not present any option to close the estimated gap between current and required spending on the SDGs of US\$2.5 trillion per year in developing countries (United Nations Conference on Trade and Development 2014). Innovative finance not only aims to establish new financial instruments but also refers to doing business in the future through more inclusive processes (SDG 17) (Porter and Kramer 2006; Ritzén and Sandströma 2017). Instruments that are complementary to grants or financial stimuli may help to unlock the additional capital needed to support sustainable investments. Examples that could form part of a smarter funding mix include loans, equity, quasi-equity and guarantees, and green, blue and social bonds (Venugopal and Srivastava 2012; International Capital Market Association 2018). Global companies are being encouraged to, not only deliver financial performance, but also show how their businesses make a positive contribution to society (Porter and Kramer 2006; Downie 2017). A number of institutional investors, banks and other private-sector financial institutions have joined this appeal, reframing their strategies in asset management and shifting investment capital to companies that incorporate environmental, social and governance considerations into fundamental financial analyses (Noguer and Houillier 2010; Enright, McElrath and Taylor 2016).

Cooperative arrangements between governments and the private sector to create new financial instruments are also beginning to emerge. For example, the Federal Republic of Nigeria, Africa's biggest oil producer, in December 2017 became the first country on the continent to issue a green bond to finance projects and programmes on renewable energy micro-utilities and afforestation. The success of the first issuance of N10.69 billion pushed the government to target an additional N150 billion green bonds in 2018. This bond issuance aims to reduce Nigeria's CO<sub>2</sub> emissions by 40 per cent by 2030. Assessing the progress, evaluating the impact and sharing the lessons learned and experiences gained from such initiatives are key to successful transformative change in policies and practices (Asrar and Hurrell 2013; Premalatha *et al.* 2013).

The transformative potential of engagement and cooperation between businesses, governments and non-governmental organizations (NGOs) is also important to highlight. The Southern Africa Food Lab (SAFL) is a platform established to provide a space for diverse stakeholders from across the food system to engage in dialogue, paying particular attention to the relationship between dialogue and action (Drimie *et al.* 2018). One of these processes involved creating transformative scenarios for the future of the Republic of South Africa's food system, at the same time as the policy on national food and nutrition security was being approved (See Freeth and Drimie 2016). The scenario process brought together a diverse group of interested stakeholders across the food system, including government officials, big business and civil-society activists and legal organizations, who all navigated through their different perspectives to build the meaningful relationships that are fundamental to policy engagement and ultimately to policy change (Freeth and Drimie 2016). SAFL has also become a rallying point for partnerships between NGOs, researchers and small businesses to engage around transformative change in the food system. Many of these partnerships involve the World Wide Fund for Nature (WWF) as a boundary organization for transformative change towards sustainability (Cockburn *et al.* 2018), by increasing consumer awareness of sustainability challenges like overfishing (WWF 2014) and transcending the partisan biases that sometimes hamstring innovative interventions (Drimie and Pereira 2016). The role of NGOs as actors enabling positive change is well documented and needs to be leveraged in order to achieve the sustainable development agenda.

## 24.4 Healthy Planet, Healthy people: challenge and opportunity

A healthy planet is the ultimate foundation for supporting all life forms, including the health and well-being of humans, which depend on the viability of this life-support system. This principle is captured in the 2030 Agenda for Sustainable Development and related multilateral environmental agreements. Improving human health and well-being, food security and nutrition, social justice and economic prosperity and environmental stewardship through sustainable development is the major theme of GEO-6.

Human activities have already transformed Earth's natural systems and disrupted their self-regulatory mechanisms, with irreversible consequences for the planetary system and human well-being (Millennium Ecosystem Assessment

2005; Rockström *et al.* 2009; Intergovernmental Panel on Climate Change 2014; Steffen *et al.* 2015; Whitmee *et al.* 2015; Ceballosa, Ehrlichb and Dirzob 2017; IPBES 2018; see Part A of this report).

The Healthy Planet, Healthy People approach is key to promoting stewardship of the air, biodiversity, oceans, land and freshwater that are essential for supporting human well-being and the sustainability of Earth systems for current and future generations. Central to this approach is taking a holistic and systemic approach, whereby the identified challenges for all aspects of Earth's life-support system (e.g. clean air, freshwater, food production from oceans and land, habitats for species) are pursued together with the socioeconomic and health dimensions (e.g. gender, equity, poverty) (Commission on Social Determinants of Health [CSDH] 2008; Gordon *et al.* 2017; Dye 2018). The complex interlinkages between the different aspects of environmental change are illustrated by the 12 selected cross-cutting issues described in Chapter 4 and the synergies and trade-offs analysed in Section 22.4.2.

About a quarter of annual deaths globally are caused by modifiable environmental factors (Prüss-Ustün *et al.* 2016). Human health depends on much more than a healthy planet though. Even if it were desirable and feasible to attain a healthy, sustainable planet without addressing socioeconomic issues and the associated determinants of health, it would still leave humanity far short of the goal of healthy people (see also Section 22.2.5, on achieving the SDG target on child mortality). Socioeconomic and cultural factors have significant health impacts, through lifestyle choices, inequalities and damaging practices such as war, violence, unsafe working conditions and child labour (CSDH 2008; see Section 4.1). Therefore, the social determinants of health, including social and wealth inequalities, must also be addressed effectively (Camfield, Møller and Rojas 2015; Donkin *et al.* 2017).

As reported in Section 4.1, human health is mediated by multiple factors in the natural, social and built environments, including our perceptions of equity and safety as well as equitable access to environmental resources and human contact with nature (CSDH 2008). This perspective complements the classical definition of human health as "a

state of complete physical, mental and social well-being and not merely the absence of disease or infirmity" (World Health Organization 1948), and the practice of using well-being (Camfield Møller and Rojas 2015; Maggino 2015) together with health to incorporate the psychological, emotional and social dimensions. The multiple relationships between planetary and human systems link health and well-being directly and indirectly to the majority of the SDGs. As such, the SDGs offer the opportunity to approach human health systemically, unlike other major health initiatives that are often focused on a given disease or pandemic event.

Several frameworks have been developed in recent years to help ensure that research and policy development take account of the complex interrelations between health, socioeconomic and environmental factors (Buse *et al.* 2018). However, much of the scientific evidence about the effect of the environment on human health has a narrower focus, on pollution and disease (i.e. mortality and morbidity), with limited attention to the wider concept of well-being or to the social determinants of health. Within this narrower classical framework of environmental health, the commission on pollution and health of the journal *The Lancet* (Landrigan *et al.* 2017) estimated that environmental pollution caused about 9 million premature deaths in 2015; mainly from outdoor and indoor air pollution, which together caused 6.4 million deaths (Cohen *et al.* 2017). Also, environmental pressures and their impacts on health and well-being are not equitably distributed (see Part A). They especially hit groups that are already vulnerable or disadvantaged, such as younger, older and female demographic groups, poor people, those with chronic health conditions, indigenous people and those targeted by racial profiling (Solomon *et al.* 2016; Landrigan *et al.* 2017).

The cost of failing to address the challenges of poor environmental conditions must be examined and communicated widely (Haines 2017; see the example in **Box 24.1**). Such costs are pervasive, through the loss of life and property; disability; the costs incurred from cardiovascular and respiratory diseases; the costs of health damages due to the multiple stresses of extreme weather events, to conflicts over food and water insecurity; gross inequality and poverty; and the tragic plight of refugees around the world.

#### Box 24.1: The health benefits outweigh the costs of implementing the Paris Agreement

The costs of implementing the Paris Agreement (UNFCCC 2015) between 2020 and 2050 could be outweighed by the health benefits of reductions in air pollution-related diseases and deaths alone, according to one modelling study (Markandya *et al.* 2018). The study modelled emission levels under various scenarios and estimated the costs of the consequent air pollution-related deaths (as a result of respiratory diseases ranging from acute lower respiratory tract infections to chronic obstructive pulmonary disease and heart disease, stroke and lung cancer), and compared this with the costs of climate-change mitigation by country or region (the People's Republic of China, the European Union, the Republic of India, the United States of America and the rest of the world). The scenarios include doing nothing, continuing current country-level policies, and three different strategies for implementing and funding the agreement towards the 2°C and 1.5°C warming limits.

Depending on the scenario used, the health benefits from reduced air pollution were estimated to be, at the global level, 1.4 to 2.5 times greater than the costs of mitigation. The highest benefit-to-cost ratio was for the emission strategy to reach the 2°C target: global health savings were estimated to be US\$54.1 trillion, dwarfing the global policy costs of US\$22.1 trillion.

Under all the scenarios examined, the countries likely to see the biggest health savings from improved emission-reduction measures were China and India. The cost of implementing climate-mitigation policies in China and India would be fully compensated for by the health savings under most scenarios, and the added costs of pursuing a 1.5°C target instead of 2°C could generate substantial benefits (for India, about US\$3.3-8.4 trillion and for China, about US\$0.3-2.3 trillion). For the European Union and the United States, the health savings would be large, but not enough to fully compensate the costs.

All of these contribute to inequality and instability and they are all far less expensive to prevent than to react to, in an attempt to manage consequences.

No nation is isolated from the impact of poor environmental conditions. To successfully advance policies, practices and financial investment in global development as well as address environmental challenges, justifications must be framed holistically based on how they can improve the security, prosperity and well-being of citizens and nations globally; policy options and sound solutions should be backed by economic analysis and data to demonstrate the savings and/or the new sources of revenue (Haines 2017; Markandya *et al.* 2018).

In the view of the public health authors of the joint commission on planetary health of the Rockefeller Foundation and *The Lancet*, “solutions [to the environmental crisis] lie within reach and should be based on the redefinition of prosperity to focus

on the enhancement of quality of life and delivery of improved health for all, together with respect for the integrity of natural systems” (Whitmee *et al.* 2015).

The changes needed to ensure a Healthy Planet, Healthy People are on such a scale and are so complex and extensive that it would be presumptuous to claim that they could be foreseen in full. Nevertheless, investing in the global environment, development and human health through multilateral agreements and actions, and building the wide coalitions that are necessary for transformative change, are certainly elements of an effective path to holistically addressing these transboundary challenges. The theme of Healthy Planet, Healthy People embodies this integrated approach to the contemporary environment and to addressing the socioeconomic and health challenges faced by current and future generations wanting a sustainable planet for themselves, their children and for all life on Earth.

# PART D

## Remaining Data and Knowledge Gaps

---

### 25. Future Data and Knowledge Needs

# Chapter 25

## Future Data and Knowledge Needs

**Coordinating Lead Authors:** Florence Daguitan (Tebtebba, Indigenous Peoples' International Centre for Policy Research and Education), Charles Mwangi (Global Learning and Observations to Benefit the Environment [GLOBE] Program), Michelle Tan (ADEC Innovations)

**Lead Authors:** Graeme Clark (University of New South Wales), Daniel Cooper (University of Oxford), James Donovan (ADEC Innovations), Sheryl Gutierrez (ADEC Innovations), Nina Kruglikova (University of Oxford), Pali Lehohla (Pan African Institute for Evidence), Joni Seager (Bentley University), William Sonntag (Group on Earth Observations)

**GEO Fellow:** Amit Patel (Planned Systems International, Inc.)

## Executive summary

**Citizen science is providing unprecedented opportunities for engaging the public in collecting and analysing vast amounts of environmental data** (*well established*).

The potential for massively dispersed teams of observers, coupled with new technologies such as smart sensors, mobile telephony, Internet and computing capabilities, is offering new approaches for research and engaging the public on environmental issues. As well as collecting large volumes of data, the advancement of new technologies has also enhanced the quality and veracity of the data collected. Key opportunities presented by citizen science include greater frequency of data from dispersed sources, the ability to address large knowledge and funding deficits, the ability to educate the public about environmental policy issues, and the use of local knowledge. {25.2.1}

**Big data is one of the world's emerging valuable resources, shifting the landscape of environmental assessment at global, national and local scales** (*well established*).

Traditional processing techniques cannot handle the volume, velocity, variety and veracity of big data, demanding new algorithms, programming and statistical methods to derive information and draw evidence-based conclusions. There is enormous potential for advancing environmental knowledge if big data can be effectively harnessed and interrogated. {25.2.2}

**Governments, organizations, academia and the private sector have initiatives seeking opportunities to tap the potential of big data for sustainability and development** (*well established*).

Current initiatives include the establishment of the United Nations Pulse Labs for pilot studies on big data, the formation of the United Nations Global Working Group on Big Data in monitoring the Sustainable Development Goals (SDGs), and the availability of repository sites and open data sources from multilateral organizations, research centres and government collaborations. Big data from web-based and geospatial mapping technologies, remote sensing and statistical visualization provide a basis for environmental assessment. {25.2.2}

**Challenges for using big data in environmental assessments include its accessibility, quality, varying scale and context, and incomplete time series** (*well established*).

Despite efforts to generate globally acceptable and available big data, capacities are limited by resources and funding, especially in developing countries. Much real-time big data are controlled and held by the private sector, though many data products are made freely available for public good in a process known as data philanthropy. Recommendations for building a holistic system for big data include the establishment of leadership and data governance; collaborations among governments, institutions and the private sector; and institutionalizing legal frameworks with safeguards on information. {25.2.2}

**Strengthening the ability to gather, interpret and use data for effective planning, policymaking, management and evaluation could provide countries with a comprehensive view of environmental impacts** (*well established*).

Governments and society need to adapt to the evolving data landscape, including the possible use of artificial intelligence to manage environmental concerns. Coping with the shift in the data landscape entails new information-technology skills and a holistic approach in utilizing emerging and existing data and knowledge tools. {25.3}

**Traditional knowledge held by indigenous peoples and local communities is increasingly seen as a valuable resource for environmental assessment and sustainable development** (*well established*).

This revaluation is evidenced by the increase in discussions and studies on traditional knowledge, and its inclusion in global policy agreements. In order to address current and future challenges such as climate change, research suggests that the best approaches may be characterized by the coordination of modern science and technology with traditional knowledge. While cooperation between local and global communities and knowledge systems has proven to be successful for the health of individuals and the planet, certain challenges remain. {25.2.3}

## 25.1 Introduction

This chapter discusses emerging areas of environmental information and statistics, including citizen science, big data and traditional knowledge. It aims to summarize the gaps and opportunities for improving the environmental knowledge base.

The global landscape is changing, technology is advancing and more and more data are available. These new data sources will not override the need for traditional means of data collection but will provide additional opportunities for environmental monitoring and assessment. This chapter analyses these new and emerging means of data collection and presents a perspective for the future of environmental monitoring and assessment.

## 25.2 Emerging tools for environmental assessment

Citizen science, big data and traditional knowledge are not new sources of information; what is new is their regular and systematic use in environmental assessments. This section highlights some current experiences and the need to use these innovative sources of information to fill data gaps.

### 25.2.1 Citizen Science

Citizen science entails the engagement of volunteers in science and research. Volunteers are commonly involved in data collection, but can also be involved in initiating questions, designing projects, disseminating results and interpreting data (Blaney *et al.* 2016). Coupling Citizen Science with new emergent technologies is providing unprecedented opportunities for doing research and sensitization of the public on environmental issues (Newman *et al.* 2012, p. 298).

The possibility of tapping into a massive, dispersed team of observers in different regions of the world has created opportunities for collating and analyzing data at unprecedented spatial and temporal scales. Citizen Science projects have the potential to gather large amounts of scientific data but this is only helpful if data collected is utilized in one way or the other (Dickinson, Zuckerberg and Bonter 2010; Kim *et al.* 2011; Dickinson *et al.* 2012).

Citizen science has numerous benefits, the main one being the opportunity to collect data over wider spatial coverage and longer periods at lower cost. Additional benefits include the creation of jobs, increased scientific literacy, citizen engagement in local and environmental issues, cost effectiveness for governments and benefits to the environment being monitored. Citizen Science also allows the expertise of scientists to be brought to the public while at the same time exposing the scientists to the indigenous knowledge and expertise available within the local community (Conrad and Hilchey 2011; Blaney *et al.* 2016). Some of the key benefits of citizen science are highlighted in **Figure 25.1: Selected targets and their related clusters as examined in this chapter**.

The fields of astronomy and ornithology have led the charge for citizen science. In 1900, Frank Chapman, an ornithologist with the American Museum of Natural History initiated the Christmas Bird Count (CBC). This project has survived thanks to the enthusiasm of citizen scientists over the years and is currently being run by the National Audubon Society (Dickinson, Zuckerberg and Bonter 2010). Since then, there have been many citizen science projects over the years at local, regional and global scales, covering different areas of interest.

More recently, citizen science projects have included a wide variety of initiatives, ranging from building collaborative knowledge (e.g. Wikipedia, OpenStreetMap), volunteer computing (e.g. CitizenGrid, climateprediction.net), and pattern classification (e.g. Galaxy Zoo, eyewire), to the community collection of observations (e.g. bird counting, air sensor toolbox) (Mathieu *et al.* 2016).

Many environmental interests that transcend government boundaries, such as pollution and bird migration, have increased the engagement of citizen scientists to monitor these issues of concern. More innovative projects include the use of Google's reCAPTCHA, which has facilitated the digitization of books and millions of articles by turning words that cannot be read by computers into CAPTCHAs for people to solve (Conrad and Hilchey 2011; Google 2018).

There are two main approaches used in the organization of citizen science projects; top-down or bottom-up. These approaches are similar to the concepts in Chapter 10 on evaluation of policy effectiveness.

**Figure 25.1: Some of the benefits of citizen science**

#### Individual Citizen

- Learn observational and analytical skills
- Gain a better understanding of the natural world
- Job opportunities
- Capacity building

#### Governments

- Lower cost of data collection
- Wider spatial and temporal coverage of data
- Promote environmental stewardship

#### Communities

- Monitor the health of the environment
- Increased interaction of the community
- Promote environmental stewardship

#### Scientists and Researchers

- Large numbers of participants reduce workload
- Scientists are able to build connection with community
- Teach people how to research

The top-down approach is mostly driven by scientists who train volunteers on the procedures and the research to be undertaken. Based on this approach, the volunteers play limited roles mostly in data collection. The bottom-up approach is driven by the community. More often than not, this is driven by the need of the community to understand or gather evidence of a concern. The community can then approach scientists for support and guidance during the process (Roelfsema *et al.* 2016; Shirk *et al.* 2012).

The level of engagement, skills and knowledge needed by volunteers to participate in citizen science projects varies depending on the scope of the research. Some projects require basic data collection knowledge requiring minimal or no training of volunteers, while others require intensive training (Haklay 2013; Shirk *et al.* 2012). **Figure 21.4: Future projections of global average crop yield (top left), crop production (top right), agricultural area (bottom left), and forest and other natural land area (bottom right)**, illustrates the various levels of engagement of volunteers in citizen science projects.

Citizen scientists can help to uncover critical information about our environment which could possibly take scientists years to discover by themselves. An example is illustrated by the infographic shown in **Figure 25.3** where rivers need a citizen science movement for monitoring, and how the collected data and findings are used to maintain ecosystem

services and human wellbeing (Pottinger 2012). The figure also demonstrates a step-by-step procedure for conducting citizen science. This data collection and analysis procedure can be replicated across the Drivers (Chapter 2) and the various environmental themes (Chapters 5 to 9).

#### Trends in citizen science

The technology revolution has heralded multiple novel ways of collecting, archiving, analyzing, and transmitting data. The emergence of the internet-of-things (IoT), miniaturized smart sensors with geo-location functions, ease of accessing internet and data as well as the potential of cloud storage and computing has expanded the possibilities and opportunities for data collection and analysis. This rapid advancement in technology coupled with greater exposure and sensitization of the public, have led to an explosion in uptake of projects based on citizen science (Mathieu *et al.* 2016).

The availability of internet and geographic information system (GIS)-enabled web applications has enabled citizen scientists to collect large volumes of geographically-referenced data and submit them electronically to centralized databases. An example of such a system is the Global Learning for Observation to Benefit the Environment (GLOBE) program, which uses students to collect environmental data and archive it in the GLOBE program database (Dickinson *et al.* 2012; GLOBE 2018).

The expansion in the use of smartphones, the possibility of digital photo validation of observations, and the capability of creating simple online data-entry systems is revolutionizing the process of initiating citizen science projects while ensuring data accuracy at minimal cost. Currently, it is now possible to create mobile phone apps for collecting different types of datasets and automatically geo-locating the data, using the in-built GPS receiver chip on most mobile phones (Dickinson, Zuckerberg and Bonter 2010; Dickinson *et al.* 2012).

Scientists are now increasingly using citizen scientists to collect geo-referenced *in-situ* data which can be used to support the calibration and validation of Earth Observation satellite data products. Citizen scientists are also involved in the interpretation and digitization of Earth Observation (EO) data sets (Mathieu *et al.* 2016; See *et al.* 2016). Tomnod is such an example of using crowdsourcing and citizen scientists to identify objects and places in satellite images. Tomnod was used in trying to locate the missing Malaysian Airlines flight MH370 aircraft using satellite imagery. Approximately 2.3 million Internet users submitted 18 million tags for over 745,000 satellite images clearly illustrating the potential of citizen science (Mazumdar *et al.* 2017).

Another example of the use of citizen scientists to validate satellite data is the partnership between NASA's Global Precipitation Measurement (GPM) satellite mission and the GLOBE program. The GLOBE program is an environmental

**Figure 25.2: Levels of citizen science by increasing depth of the participation**

**Figure 25.3: An example of citizen science that demonstrates how it is needed and can be replicated**

### Case Study: Why our rivers need a citizen science movement

Most of our decisions are based on incomplete or inadequate data/information - in the absence of professional scientists to fill these gaps, citizen science can step in to help uncover information and findings. This case study explores opportunities where citizen scientists have filled this gap.

#### TOO MUCH WORK, TOO FEW SCIENTISTS

- There is too much research that needs to be done yet hardly enough scientists to undertake it all by themselves.
- Volunteers in the US state of Oregon are helping scientists survey 146 miles of streams by locating and counting salmon and native trout species and helping restore habitat.
- Hundreds of volunteers with The Nature Conservancy annually survey how much desert land is made wet by the San Pedro River; they cover more than 250 miles.

#### BECAUSE THEY'RE OUR RIVERS

- Volunteers for the Mystic River Watershed Association in the Eastern US, with support of scientists, take monthly samples at 15 locations along the river to monitor water quality.
- Advocacy based on their results has helped improve the river's cleanliness and has enabled the residents get involved in their natural environment through hands-on science.

Just **1 in 10** rivers now reach the sea

**8/10** people depend on river resources

Just **2/3** of Earth's major rivers are dammed

#### WHAT WE DON'T KNOW CAN HURT US

- Citizen science can be used to document basic information about a river system, as well as changes over time to its flow, sediment load, species and water quality.
- In China, the South-North Water Transfer Project was envisioned to have massive impacts on many key waterways, volunteers were recruited for a 4 year assessment of 10,000km of China's western rivers.

#### UNCOVERING RIVER MYSTERIES

- Citizen scientists can fill in gaps in crucial baseline knowledge about a river's species or general health.
- The Mekong River in Southeast Asia supports several species of giant fish and very little is known about them. More information is needed on where they spawn, what natural cues drive them to spawn, population estimates, and maps of their life-cycle territory.
- A step-by-step guide on Mekong River citizen study illustrates how this can be realized.

### STEP-BY-STEP CITIZEN SCIENCE GUIDE: CASE STUDY OF FISHING VILLAGERS DOCUMENTING MEKONG'S RIVER'S NATURAL WEALTH

#### IDENTIFY THE QUESTIONS YOU WANT TO ANSWER

- In 1994, Thailand built Pak Mun Dam on the largest tributary of the Mekong, destroying local fisheries and harming river-based communities.
- Information on local fisheries was scant.
- In 2001, the Thai government opened the dam's floodgates 1-year study of its impacts to fisheries.

#### FORM A RESEARCH TEAM

- South East Asia Rivers Network (SEARIN) and Assembly of the Poor teamed up to monitor the changes caused by the dam.
- Their innovative citizens' science research method, called Thai Bahn (Thai Villager) research, relied on local fishers to gather information.

#### DEVELOP A PLAN OF ACTION

- Methods, areas of study, and research team members were all decided by the local villagers.
- SEARIN helped develop a plan of action, write up their findings and increase international awareness.

#### DOCUMENT YOUR FINDINGS

- The natural flows of the one-year trial period allowed people to resume traditional ways of life and eased resource conflicts among river communities.
- Local fish species not seen for eight years came back; researchers found a total of 156 fish species had returned to the Mun River.

#### ANALYZE YOUR DATA

- SEARIN helped create a report on the team's findings, in two languages.
- The report is considered one of the most thorough documentations of Mekong fisheries produced for that area.

#### SHARE YOUR FINDINGS, AND USE THEM FOR ACTION

- Thanks to this citizen science effort, the villagers succeeded in getting the Thai government to open the dam gates for four months each year to allow for fish migration.
- Subsequent governments have not implemented this agreement.
- The project has inspired many other citizen science projects to protect rivers in the region.

data (United States National Aeronautics and Space Administration [NASA] 2018).

Automated and autonomous equipment such as drones, remotely operated sensors, autonomous underwater vehicles (AUV's) and underwater gliders are predicted to play an increasing role in citizen science. These autonomous systems can be a primary source of data or complement data collected *in situ*, provide high resolution data nearly in real time, be deployed on a need basis and often enable access to remote or extreme locations such as observation of marine environments. In addition, they are low cost compared to satellites and are thus offering alternative and credible sources of EO data (Macauley and Brennan 2016; Garcia-Soto 2017).

Citizen science, as well as other data sources, contributes to Big Data collection and these huge volumes of data need processing. Numerous approaches have been explored to involve the huge numbers of citizen scientists to assist in analyzing these huge volumes of data, one of which is the development of game-like systems (gamification). Citizen participation in these games help to speed up the data analysis and allow science to advance more rapidly (Van Vliet and Moore 2016; Spitz *et al.* 2017; McCallum *et al.* 2018).

An example of gamification is Cropland Capture, a game version of the GeoWiki project, which engaged citizen scientists in global land cover research, helping researchers identify farmland around the world. The game managed to collect 4 million classifications from over 3,000 players identifying images with and without cropland present (See *et al.* 2013).

**Table 25.1** shows some of the global and regional projects dedicated to citizen science.

The potential of citizen science should not be limited to engaging volunteers to collect and collate scientific data as illustrated in **Figure 25.5**. Citizen science can be used to sensitize and engage the community on issues related to their natural environment, to better understand them and allow them to take charge, and provide an avenue for showcasing the need

**Table 25.1: A selection of citizen-science projects and websites**

to maintain and conserve our ecosystems given the increasing pressures on the environment (Roelfsema *et al.* 2016).

### **Challenges of citizen science**

Challenges in citizen science mostly revolve around three main issues: *organizational* issues, *data-collection* issues and *data-use* issues. At the organizational level, the challenges include the process of recruiting volunteers, motivating and providing incentives for their participation and ensuring sustainability of the initiative as well as funding. On data collection, the issues that arise include: data fragmentation, data representativeness, data quality (for example data intentionally flawed by the data collector) and/or lack of essential metadata. In data use, the challenges include: differences in protocols and standards, legal issues, data-privacy concerns and the question of allowing open access (Conrad and Hilchey 2011; Hochachka *et al.* 2012; Rotman *et al.* 2012; See *et al.* 2016)

Due to misunderstandings and lack of technical knowledge and skills to handle such data, concerns have emerged over the credibility, comparability, completeness of, and lack of metadata, as well as challenges in data access and sharing, and these have resulted in these data not being seriously considered by policy and decision makers. In most cases,

perception of poor data quality, rather than the actual data quality and fitness for use, have influenced the value and use of citizen science data (University of the West of England, Science Communication Unit 2013; Storksdieck *et al.* 2016).

The key opportunities presented by citizen science, mainly include:

- i. use of local knowledge;
- ii. timely data from dispersed sources;
- iii. capability to address large knowledge and funding deficits;
- iv. ability to educate the public about environmental policy issues; and
- v. enhance participatory democracy.

For citizen science to be widely accepted, there is a need for appropriate training and support for citizen science project coordinators and those that use the data that emerge from it. Careful design of citizen science projects and application of appropriate quality assurance methods, as illustrated in **Figure 25.3**, can ensure that the effort of citizen scientists is not wasted (University of the West of England, Science Communication Unit 2013; Storksdieck *et al.* 2016).

There are on-going initiatives, such as the Public Participation in Scientific Research (PPSR)-Core data model framework as illustrated in **Figure 25.6**, to establish data and metadata standards to facilitate international collaboration and improve data standardization, interoperability, integration, accessibility, and dissemination of citizen science data (Bowser *et al.* 2017). Citizen science has the potential to provide credible data to bridge the data gaps highlighted in Chapter 3 and to provide data to enable the monitoring of SDG environmental indicators.

### 25.2.2 Big data and data analytics

Big data can be defined as “datasets whose size is beyond the ability of typical database software tools to capture, store, manage and analyze” (Manyika *et al.* 2011).

Data are one of the world’s valuable resources, shifting the landscape of environmental assessment across global, national and local scales (“The world’s most valuable resource is no longer oil, but data” 2017). From 1.8 zettabytes (1.8 trillion gigabytes) of data generated in 2011 (International Data Corporation [IDC] 2012), the total amount of data is expected to reach 40 zettabytes (40 trillion gigabytes) by 2020 (Dell EMC and IDC 2014). With this influx, traditional processing applications will be unable to cope with the quantity of data from multiple sources. Big data is characterized by the four Vs of large storage capacity (volume), speed at which data are generated and transmitted (velocity), the complexity of unstructured data types (variety), and the uncertainty of data sources (veracity) (**Figure 25.7**). A fifth V (value) is achieved through the application of data analytics (International Business Machines [IBM] 2017).

The science of data analytics is needed to create patterns from intricate data sets and find correlations (e.g. chemical pollution and locations in aerial photographs) by using algorithms, programming, and mechanical and statistical methods to draw evidence-based conclusions and obtain information that is useful for decision-making purposes (Monnappa 2017). Examples of insights drawn from big data analytics include those from projects in the United Nations Global Pulse initiative, such as:

- i. urban dynamics drawn from mobile data used to improve transportation in Sao Paulo and Abidjan;
- ii. campaign developments based on a survey of perceptions of HIV on social media; and
- iii. and a support-services location plan based on the spatial epidemiology of Dengue fever (Kirkpatrick 2016).

#### Current trends and initiatives in big data

United Nations member states, in partnership with the academic and research communities, non-governmental organizations and the private sector, are seeking out innovations and looking for opportunities to tap into the optimum potential of big data for sustainability and development.

#### Innovation for public good

The United Nations Global Pulse initiative was founded in 2009 to progressively establish a global network of Pulse Labs to collect digital data for decision-making purposes (United Nations 2018a). Pulse Labs continue to innovate machines and to conduct pilot studies on the scalability of the capture and analytics of big data for sustainable development – some examples are presented in **Table 25.2**.

In recognition of the significance of big data for official statistics, the UN Statistical Commission (UNSC) established the UN Global Working Group (GWG) on Big Data in 2014 to tap the potential of big data in monitoring the SDGs. Various collaborations, research and projects addressing the quality, collection, accessibility, management and feasibility of big

data have been developed over the years. These have included task-force teams focusing on the relevance of large volumes of information coming from mobile phones, satellite imagery, social media, virtual platforms and technological applications (United Nations 2018c).

Other initiatives of the United Nations include the UN Environment Live platform (**see Table 25.1**), which in addition to a repository related to citizen science has data from official national, regional and global statistical and geospatial data series on different thematic areas (freshwater, forests, climate etc.). Another example is the Sustainable Development Goals Interface Ontology (SDGIO), developed by UN Environment to harmonize the relationships across different SDGs through a taxonomy and semantic framework, for SDG monitoring purposes (Jensen 2017).

#### Data collaboratives

Governments, leading technology companies, innovators, academia, research institutions and non-governmental organizations are convening to understand the challenges around big data and to search for development solutions through collaborative learning. The UNSC Global Working Group believes that a multifaceted approach to data collection, leading to timely delivery of trusted information, can be made possible through close relationships among the private and public sectors, including civil society (United Nations 2018c). Such dialogues open doors for the co-creation of more innovation hubs, allowing capacity-building and skills transfer from countries with more experience in big data to those entering the field more recently (e.g. Vacarelu 2017).

#### Open data access

Access to open data is essential to harnessing big data's potential for sustainability and development. The global

non-profit network Open Knowledge International and the World Wide Web Foundation's Open Data Barometer promote open data as accessible, readily available and free of charge for universal use (World Wide Web Foundation 2017). Open access to valuable and timely data from the outputs of surveys, field experiments and scientific research provides a powerful resource for presenting the state of the environment, validating our knowledge of the anthropogenic climate-change impacts, and towards proposing feasible solutions.

**Box 25.1** presents a selection of open-data initiatives at global and national levels.

#### Environmental assessments and evaluation

Big data analytics enable illustrations of trends and progress over time (e.g. comparing current with historical data at a specific spatial site), reaches more end users beyond geographical boundaries, and allows a predictive analysis of the future using models and comparisons with historical data. Web-based and geospatial mapping technologies, remote sensing and statistical visualization provide a basis for analysis of environmental implications and raise issues on the scalability of data collected, as reflected in the sample of assessments and evaluations in **Box 25.2**. Big data from satellite imagery and sensors make the environmental indicators measurable (Uitto 2016).

The Data-Pop Alliance describes big data as a socio-technological phenomenon, emerging from a novel data ecosystem that defines the complexity of human behaviours and beliefs – generated and captured by digital devices, computational and analytical tools, and the active correspondence of communities (Anttila-Hughes *et al.* 2015). With this paradigm shift, technology has been used to survey public insights, leveraging big data to improve the environmental process.

#### Box 25.1: Examples of open-data systems

##### National Bioscience Database Center

National database of Japan, containing global life sciences data that can be readily accessed by users.

##### Air Now

A global database that presents the daily nationwide forecast of the Air Quality Index (AQI) of over 400 cities, providing visual representation of the air quality condition relevant to health interpretation.

##### Open Data for Business Assessment and Engagement Tool

Launched by World Bank in 2016 to establish the use of open government data for industrial or business purposes.

##### Estonia's X Road

Online e-government system, serving as a platform of data exchange among participating institutions and private companies, with 70 per cent composed of government agencies.

### Box 25.3: Comprehensive air-quality forecasting in India using big data

There are several hundred manuals and about a hundred regulatory air-monitoring stations in operation in India. These are limited to urban agglomerations, so second-tier towns and rural areas do not have access to any on-ground monitoring data. Before being able to manage and improve air quality effectively, citizens and policymakers need to know the status of air quality and to have information on the sources of pollution. The system, known as India air-quality forecasts, developed by [urbanemissions.info](http://urbanemissions.info), uses a modelling approach to predict, for the next three days, the estimated pollution levels and source contributions for all of the 640 districts in India. This is not a substitute for a robust monitoring system, but the estimates can be used to support informed decision-making while more monitoring capacity and systems are built.

While the methodology is continually improving, the key challenge in this approach is using a detailed emissions inventory and its spatial and temporal granularity. The programme currently uses information from official reports, academic publications, and survey analysis, and the following open data (dynamic feeds), which are updated every day.

- ❖ Remote-sensing satellite data (from NASA's Visible Infrared Imaging Radiometer Suite) for location of open fires, which when overlaid with land-use imagery, builds a dynamic emissions inventory for agricultural and forest fires at 1 km resolution.
- ❖ Meteorological data at 1 km resolution linked to emissions from multiple sectors. For example: (a) a surface temperature profile is used to trigger space heating in the residential sector (b) grids with precipitation over 1 mm/h are adjusted for lesser vehicle movement (c) grids with precipitation are adjusted for dust resuspension on the roads and dust at the construction sites (d) the dynamic calculations within the meteorological model estimation of likely dust storms, sea salt emissions, lightning, dry deposition rates and wet scavenging rates by grid.
- ❖ Google provides a wealth of information on traffic movement. Over cities, transit speeds are extracted at 1 km resolution, which is used as a proxy to dynamically allocate vehicle exhaust emissions and estimate road dust resuspension. For example, during peak times, if a grid shows speeds under 5 km/h, the emissions profile is adjusted to increase the exhaust emissions due to idling, and the road dust resuspension is zeroed.
- ❖ Google Earth imagery is used to generate spatial data on brick kilns, power plants, industrial zones, and mining and quarrying areas.
- ❖ Load dispatch centres across India report information on demand and supply by power grid, which is used as a proxy to dynamically adjust the use of diesel generator sets in cities.

These dynamic feeds are making air-quality forecasting more robust, allowing the model to capture trends, and they help to understand the source contributions better. Multiple microsensor networks are being tested and evaluated in several cities, promising to further improve the forecasting process and strengthen the on-ground data availability.

### Challenges in Big Data

Gaps in the collection, monitoring, analysis and interpretation of data identified in GEO-5 continue to challenge the reliability of Big Data as a tool in environmental assessment today in GEO-6. Issues include the accessibility, quality and sparsity of data for varying scales, contexts and time series (United Nations Environment Programme [UNEP] 2012). Constraints, generally encountered across the thematic areas covered in GEO-6, are summarized in **References**. These challenges on scope, privacy and potential for misinterpretation of data have not been sufficiently addressed over the years. Efforts to generate globally acceptable and available Big Data are pursued, but the actual capacities are limited by scarce resources and funding, especially in developing countries.

Although the private sector has been pioneering Big Data strategies, increasingly governments and global initiatives are exploring the benefits of Big Data for transparency, market analysis, research, education and environmental protection. In South-East Asia, six countries have formed an open-government partnership to advance their vision of scaling up public services and leveraging Big Data for development (Bhunia 2017).

Environmental agreements provide United Nations member states with guidelines on how to make environmental data publicly accessible, and provide open, geographically referenced data, together with opportunities for public

participation in decision-making, multi-stakeholder involvement and the promotion of government transparency and accountability. These agreements include the Aarhus Convention on Access to Information, Public Participation in Decision-Making and Access to Justice in Environmental Matters (United Nations 1998) and the *Kyiv Protocol on Pollutant Release and Transfer Registers* (2003). The Data-Pop Alliance is a global coalition for people-centred data pioneered by the Harvard Humanitarian Initiative, Massachusetts Institute of Technology Media Lab, and the Overseas Development Institute. This alliance, funded by the United Nations Economic Commission for Latin America and the World Bank Group among others, creates a collaborative workspace for researchers, experts, practitioners and activists to overcome foreseen challenges on Big Data (i.e. technological biases, lack of access to an online knowledge-sharing facility, and limited technical capacity development) through research, capacity-building and community engagement (Data-Pop Alliance n.d.). A 2015 report by the alliance explores the opportunities for leveraging Big Data to monitor climate change hazards, mitigate the impacts, guide disaster response and increase the resilience of vulnerable countries (Anttila-Hughes *et al.* 2015).

Real-time Big Data are often controlled and held by the private sector (Kirkpatrick 2016). Therefore, collaborations are needed where both parties benefit without sacrificing the economic value of data, and at the same time maintain fair competition among businesses. The private sector has been providing the public sector, including research institutions and industry practitioners, with access to data through what Robert Kirkpatrick (2016) describes as data philanthropy. This collaboration has been in existence within the United Nations system. In pursuit of companies' contributions to SDGs, data scientists at the firms interpret private data for public good and well-being, which, in return, reduces the risks to business. Another form of collaboration is the public-private partnership where resources and capabilities on Big Data are shared between governments, National Statistical offices, research institutions, and the private sector, including leading technology and data companies across the globe. **Table 25.3** presents some examples of economic improvement achieved through public-private partnerships.

For Big Data to become an effective tool for environmental assessment and development, this emerging form of data and knowledge should be seen as a valuable asset. Big-data analytics involve not only compiling information but also creating a comprehensible view of the environment and its social attributes as a basis for proposing solutions and drafting policies. Factors that contribute to establishing a holistic data system include leadership and data governance, including the appointment of a chief data officer in national and local government agencies; partnerships among governments, institutions and the private sector; and institutionalizing legal frameworks with safeguards on information.

### Box 25.4: Some challenges of using Big Data

#### Big Data Challenges

##### Accessibility

Reluctance of governments and private sector from sharing information lead to data disintegration. Most data in the private domain are bounded by privacy and security limits-intellectual property rights, thus entailing a price for accessibility. Data sharing and availability are not only part of the legal issues, but of the political concern as well-like in China where the government place restrictions in the release of valuable environmental information.

##### Quality

There is no assurance in the reliability of data due to inconsistencies in the methodologies used by different countries and insufficient technical capability on data interpretation and analysis. Baseline studies are paralyzed by insufficient valuable data (e.g. biodiversity, hydrometeorological, wastewater treatment).

##### Sparsity

The availability of data varies across temporal and spatial scale. To fill the gaps, researchers utilize secondary information as proxy data and model estimates to fill the gaps, making global data incomparable.

**Table 25.3: Example public-private partnerships**

| Partnership                                                                           | Project description                                                                                                                                                                                | Source                     |

### 25.2.3 Traditional knowledge

Many terms are used to describe the knowledge held by indigenous peoples and local communities. Some refer to the term traditional ecological knowledge, which is “a cumulative body of knowledge, practice, and belief, evolving by adaptive processes and handed down through generations by cultural transmission, about the relationship of living beings (including humans) with one another and with their environment” (Berkes, Colding and Folke 2000, p. 1,252). Others prefer to use the terms indigenous knowledge, folk knowledge, local knowledge or traditional knowledge. There is no universally accepted definition of the diversity of expressions within this epistemic landscape; however, to include the widest understanding, this section uses the term traditional knowledge to include ecological, local, indigenous and folk knowledge.

According to Article 8j of the Convention on Biological Diversity, traditional knowledge includes cultural values, beliefs, rituals, community laws, local language and knowledge related to practical fields such as agriculture, fishing, hunting, medicine, horticulture, forestry and environmental management in general (Secretariat of the Convention on Biodiversity n.d.). The following definition, meanwhile, was published by the World Intellectual Property Organization (WIPO) in 2010 and remains the description given by the body (WIPO n.d.): “knowledge, know-how, skills and practices that are developed, sustained and passed on from generation to generation within a community, often forming part of its cultural or spiritual identity”.

Perceived by some in the mainstream as superstitious and anecdotal, traditional knowledge has been historically marginalized. In the past 20 years, however, it has been acknowledged as a valuable resource for sustainable development. Its promotion and protection has been expressed in several United Nations agreements and agencies (e.g. Article 8(j) mentioned above, the United Nations University Institute for the Advanced Study of Sustainability, and WIPO). The foundational operating principles of the Intergovernmental Science-Policy Platform on Biodiversity and Ecosystem Services, established in 2012, include recognition and respect

for the contribution of indigenous and local knowledge to the conservation and sustainable use of biodiversity. Moreover, the United Nations Convention to Combat Desertification (UNCCD) in its Decision 20/COP.12 adopted “improvement of knowledge dissemination including traditional knowledge, best practices, and success stories” (UNCCD 2016, p. 57).

An increasing amount of research concludes that traditional knowledge developed through direct interaction with local ecosystems is of equal value to that of Western scientific knowledge. Both knowledge systems have commonalities, but each has distinct features (see Figure 25.9) that complement each other to better understand the natural world (Agrawal 1995; Tsuji and Ho 2002).

**Figure 25.9: Comparing indigenous/traditional knowledge and Western science**

Source: Baker, Rayner and Wolowic (2011).

### Traditional knowledge and Western scientific knowledge

GEO-5 called for coordination in the realm of knowledge-building, which implies that cooperation is necessary between Western scientists and the various holders of traditional knowledge. Recent progress has enabled the development of new tools and approaches in measurement, reporting and verification. Among others, these include the community-based monitoring and information systems, and the multiple evidence-base system, both of which foster knowledge co-creation between indigenous and Western systems, as an important way to help advance the recognition of the leadership role of indigenous peoples in stewarding their lands and waters (Raygorodetsky 2017). See more detail about these and other approaches in **Box 25.5** and **Table 25.4**.

These approaches combine traditional community monitoring systems with modern software (e.g. GIS, Google Maps, GPS, Microsoft Excel) and hardware (e.g. drones, remote sensing

devices, trackers, smartphones, electronic tablets) to generate data and develop information on trends in ecosystems in order to assess development interventions. These modern tools and monitoring systems enable individuals and communities to decide on what actions to take by providing informed, improved and timely decision-making.

As traditional knowledge is based on *in situ* data generation, it is effectively used to give on-the-ground truth to Big Data, and like citizen science, could involve all sectors in the community.

**Table 25.5** outlines new partnerships between communities and researchers that have produced innovative new approaches to the documentation and analysis of traditional knowledge.

### Traditional knowledge and the SDGs

Indigenous peoples' engagement in the development of the 2030 Agenda for Sustainable Development (United Nations 2015) resulted in the inclusion of six references to

### Box 25.5: Complementary uses of traditional knowledge and Western science

Community-based monitoring and information systems refer to initiatives by indigenous peoples and local communities/organizations to monitor their community's well-being and the state of their territories and natural resources, applying a mix of traditional knowledge and innovative tools and approaches (Ferrari, de Jong and Belohrad 2015).

The multiple evidence-base system generates new insights and innovations through complementarities between indigenous peoples, local communities and Western scientific knowledge systems. The system emphasizes that the evaluation of knowledge occurs primarily within, rather than across, knowledge systems (Tengö *et al.* 2014).

Indigenous peoples make and use maps to: assert their rights to lands and waters; manage their territory; preserve knowledge of their own history, culture and environment; and communicate some of this knowledge to others (Tebtebba Foundation 2015).

Successful integration of traditional knowledge with modern science, technology and innovation can be seen in the example of a recent tech start-up called Indigital. This Aboriginal-owned and operated social enterprise, based in the Kakadu World Heritage Area in the Northern Territory of Australia, uses digital technology to showcase local sacred sites, knowledge and stories in augmented and virtual realities, contributing to the preservation of heritage while creating jobs in the digital economy (Cooper and Kruglikova 2018).

**Table 25.4: Studies that combine traditional knowledge with Western scientific knowledge**

| Study                                                                                                                                                                                   | Summary                                                                                                                                                                                                                                                                                    |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Genome-wide association study to identify the genetic base of smallholder farmer preferences of durum wheat traits (Biodiversity International 2017; Kidane <i>et al.</i> 2017)</b>  | The study demonstrates that researchers using modern scientific tools (i.e. genetic analysis), and holders of traditional knowledge using cultural practices in crop selection can work together to advance crop breeding to cope with the changing climate.                               |
| <b>Arbediehtu pilot project on documentation and protection of Sami traditional knowledge (Porsanger and Guttorm eds. 2011)</b>                                                         | The study highlights community work, legal questions and legislation, ethics of documentation, institutional relationships, history and identity, information technologies, transmission, management, and legitimacy.                                                                      |
| <b>Traditional knowledge and nutritive value of indigenous foods in the Oraon tribal community of Jharkhand: an exploratory cross-sectional study (Ghosh-Jerath <i>et al.</i> 2015)</b> | The study identifies more than 130 varieties of indigenous foods, many of which are rich sources of micronutrients and medicinal properties, and explains how they can be leveraged to address malnutrition in tribal communities.                                                         |
| <b>Cree traditional ecological knowledge and science: a case study of the sharp-tailed grouse (Tsuji 1996)</b>                                                                          | The study shows that Cree traditional knowledge is factual and often quantitative in nature. While limitations exist in the distinction between observations and interpretations, this knowledge can be added to databases to facilitate resource co-management.                           |
| <b>Collaborative Partnership on Forests (2018)</b>                                                                                                                                      | The project shows that the integration of traditional knowledge into forest management practices is a prerequisite for achieving sustainable forest management because it strengthens the rights and participation of indigenous peoples and local communities, and clarifies land tenure. |

**Figure 25.10: Recognition of indigenous peoples in the 2030 Agenda for Sustainable Development**

Source: United Nations (n.d.).

indigenous peoples. Aside from these six, many other SDGs address indigenous peoples indirectly, through the principles of human rights, equality, non-discrimination, sustainability, and participation by right-holders. Sustainability, as the banner of Agenda 2030, is underpinned by environmental health.

Having evolved after years of observation and experience from a holistic relationship between people and nature, traditional knowledge sustains life and landscapes. Meanwhile, current development strategies are largely based on Western science and technology, which are often detrimental to the environment and our well-being in many ways. Therefore, there is a need to harness scientific knowledge, technology, and traditional knowledge to solve many of the issues related to sustainable natural resource management and biodiversity conservation. Some examples of studies on the potential of traditional knowledge for sustainability are presented in **Table 25.5**.

**Figure 25.11: Lands/territories of indigenous peoples are the base of their knowledge**

© Tebtebba Foundation 2008.

The promotion and development of traditional knowledge is hampered by contemporary bias in existing power relations. In many places, holders of traditional knowledge continue to face exploitation when trying to defend their territories against further abuse. As a result, their lands – which constitute the basis of their knowledge systems – have been subjected to resource development projects such as mono-crop plantations for rubber, timber and palm oil, large hydroelectric dams, mineral extraction activities (Asia Indigenous Peoples Pact 2015), and conservation projects (Vidal 2016).

To address historical and continuing injustices adequately, indigenous peoples and local communities, their land, and the knowledge systems that hold these together must be included in the development process. As expressed in the United Nations

**Table 25.5: Studies on the potential of traditional knowledge for sustainable development**

| Study                                                                                                                                                                                         | Summary                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Local biodiversity outlooks: indigenous peoples' and local communities' contributions to the implementation of the strategic plan for biodiversity 2011-2020 (Forest Peoples Programme 2016). | This study presents snapshots of on-the-ground initiatives by indigenous peoples and local communities and demonstrates that they are making vital contributions to the implementation of the five strategic goals and the 20 Aichi biodiversity targets, although many challenges remain. It outlines the way forward, highlighting key potential actions to accelerate progress in the implementation of the strategic plan for biodiversity as it relates to indigenous peoples and local communities. |
| Sustaining and enhancing forests through traditional resource management (Enchaw and Njobdi 2014)                                                                                             | This study highlights women's roles in forest management and sustainable farming within the context of indigenous knowledge.                                                                                                                                                                                                                                                                                                                                                                              |
| United Nations Educational Scientific and Cultural Organization (UNESCO) World Heritage: Agricultural Landscape (UNESCO 2013)                                                                 | This study deals with communities that demonstrate rich cultural and landscape diversity and sustainable land-use systems. It also highlights how some people struggle for daily survival under extreme climatic and environmental conditions.                                                                                                                                                                                                                                                            |

Declaration on the Rights of Indigenous Peoples (United Nations, General Assembly 2007), these peoples have the right to self-determination, as well as to their land, resources and the freedom to pursue their own way of life. These rights are necessary for peoples to sustain, innovate and develop traditional knowledge systems and customary practices. Granting and implementing these rights is crucial for ensuring the maintenance of a balance between the economic, social and environmental dimensions of sustainable development.

#### **Traditional knowledge for a Healthy Planet, Healthy People**

Traditional knowledge is an invaluable resource for sustaining a healthy population and planet. Indigenous territories constitute up to 22 per cent of the world's land surface and sustain 80 per cent of the planet's biodiversity (Food and Agriculture Organization of the United Nations [FAO] 2017). The vast majority of the world's genetic resources and a considerable part of global biodiversity survives within indigenous and community-conserved areas. This correlation is not coincidental but is due to the application of traditional knowledge and the customary sustainable use of biological resources over centuries (Independent Expert Advisory Group Secretariat 2014). Moreover, the indigenous ethics and values, plus culture and identity, related to land and wildlife stewardship, hold great promise for more effective resource management as well as for more effective risk reduction in human health (Houde 2007). **Figure 25.12** is just one illustration of the wealth and potential of traditional knowledge and practices for environmental management that need to be optimized in their contribution to improving the health of both land and people.

Further examples of benefit include the many advantages of maintaining a well-functioning food web – including the enhanced diversification of wild and cultivated food systems, enhanced nutrition, and a healthy environment (Kuhnlein *et al.* eds. 2013).

However, traditional knowledge remains underutilized in environmental assessment and management. While advances have been made, there are still challenges that need to be addressed. As cited by Genetic Resources Action International [GRAIN] and Kalpavriksh (2002), these include:

- i. the continued loss of indigenous peoples' lands, making it challenging for indigenous communities to sustain their knowledge;
- ii. the risk of misappropriating traditional knowledge or patenting life forms for commercial purposes without sharing the benefits with knowledge holders, as demonstrated by the case of turmeric in India;
- iii. the proliferation and all-out promotion of so-called modern medicine and agriculture, which replace diverse plants and crops that would have been able to resist pests, diseases, and changing climatic and economic conditions (GRAIN and Kalpavriksh 2002);
- iv. the co-production of knowledge processes that do not always guarantee fairness, equal standing, or power symmetries (Williams and Hardison 2013); and
- v. the rapid erosion of linguistic diversity is accompanied by the loss of indigenous ways of knowing and understanding of the natural world (UNESCO 2017).

Other challenges relate to the full and effective implementation of free prior and informed consent (United Nations, General Assembly 2007). To address these challenges in an efficient way, policies need to be formulated and implemented on the basis of "further interdisciplinary action research that brings together indigenous knowledge holders and scientists, both natural and social, to build mutual understanding and reinforce dialogue" (Nakashima *et al.* 2012, p. 97).

## **25.3 Environmental monitoring for the future**

### **25.3.1 Measuring what matters**

There is a maxim that what gets measured gets done. Its origin is debatable, but the message is clear: measuring something gives us the information we need to make sure we actually achieve what we set out to do.

As noted in Section 3.3.1, the data requirements for the SDG indicators are almost as unprecedented as the SDGs themselves, and constitute a tremendous challenge to all countries. Unfortunately, much of the data required to monitor the SDGs are unavailable. Issues relating to quality, timeliness, human and financial capacity, and the lack of standardized methodologies all hamper our ability to comprehensively track this important agenda. As highlighted in the United Nations (2016) report on the SDGs, tracking their progress will require a shift in how data are collected, processed, analysed and disseminated, including a move to using data from new, diverse and innovative sources. More than ever, this demands that

**Figure 25.12: Indigenous peoples as stewards of the environment**

Source: FAO (2016).

we explore other data streams – citizen science, Big Data and traditional knowledge – to complement conventional, official statistics and Earth observations.

### 25.3.2 Translating local information into national data

A shift in data generation by electronic devices, data modelling, cloud computing and other technologies has produced unprecedented volumes of information. The availability of these data and information varies, however, between developed and less developed countries, between and within social groups – by gender, ethnicity, and social and income status – and markedly between the global and local levels. Data and information gathering at national and local levels is given lower priority, especially in developing countries. But to solve global problems, actions for solutions must emanate from the local and national level. Policy effectiveness should be measured according to its implementation and fulfilment at the local to national level (see Part B).

Over time, there has been an accumulation of knowledge on good and bad practices of environmental management, enabling some conclusions as to what needs to be done. However, there remains a need for making traditional knowledge more accessible and to integrate traditional knowledge with other sources of information.

On the global level, states and civil society organizations, academia, indigenous peoples and activists all agree that for the promotion of environmental protection and restoration, biological loss and climate change need to be addressed. Yet at the country level, positions about environmental protection vary, and often even contradict each other.

The SDGs aim to reduce environmental degradation while at the same time upholding basic human rights and promoting economic empowerment. This will require knowledge and technology to be shared between communities, businesses and governments – from local, through national, to global levels.

### 25.3.3 Open data and reproducible research

The open-data movement has gained significant traction in recent years and is expected to continue to grow. The concept of open data is that data resulting from publicly funded research should be freely available to all, for equity, transparency, and to catalyse the advancement of science. The principles of open data have been proposed in a number of different variations, including the Open Data Charter (2015), which stipulates that data should be:

- i. open by default;
- ii. timely and comprehensive;
- iii. accessible and usable;
- iv. comparable and interoperable;
- v. for improved governance and citizen engagement; and
- vi. for inclusive development and innovation.

There are clearly demonstrated benefits of open data, particularly in the health sector (Kostkova *et al.* 2016). The principles of open science, open innovation, open access and open source adopted by the malaria research community, for example, have allowed it to achieve more progress than would otherwise be possible (Wells *et al.* 2016). Additionally, many countries now have open government data portals that include environmental data.

There is a growing call for reproducible research alongside open data, and the two are often considered in tandem by the open-science movement. To be reproducible, research should be reported in a manner that allows it to be replicated precisely (Mesirov 2010). There are three aspects of research reproducibility – it should be:

- i. empirical – based on scientific experiments and observations;
- ii. computational – code, software, hardware and implementation details are made available; and
- iii. statistical – based on statistical tests and model parameters (Stodden 2014).

Computational and statistical reproducibility are most pertinent to data practices. In theory, the publication of code and data together means that users can understand and critique the entire process of analysis and inference, including details of the techniques used and any assumptions made. Publication of code is now an essential prerequisite of many scientific journals, and this trend is increasing such that it is expected to become the norm in coming years.

Reproducible data analyses are especially important in an era of open data, since users of data will become increasingly detached from those who collect and curate the data. Open-access data increases the risk of data being misused or misinterpreted, but the publication of code circumvents this problem in that the treatment of data is transparent and can be scrutinized by readers. Reproducibility not only improves the quality of scientific output, but also increases trust in the results, and therefore uptake (Laine *et al.* 2007).

### 25.3.4 Coping with the changing data landscape

Strengthening the ability to gather, interpret and use data for effective planning, policymaking, management and evaluation is necessary for providing countries with a comprehensive view of environmental impacts, ranging from geo-political perspectives through to industrial operations, naturally occurring or anthropogenic environmental change or a combination of all these. The challenge escalates as the magnitude and types of generated data, both structured and unstructured, grow over time. Management information systems alone are insufficient to draw the full value from the exponential growth of potential data assets. It is imperative that governments and society learn to cope with the evolving data landscape, to shift from mere reporting and conventional data repository functions towards a predictive and prescriptive analysis for both modelling different environmental scenarios and creating appropriate policies to address these foreseen challenges.

The information landscape is changing as the technologies for harnessing data evolve from data-as-a-service (DaaS) or software-as-a-service (SaaS) to insights-as-a-service (IaaS), which uses prescriptive analytics (**Figure 25.13**). With DaaS, data could reach several users beyond geographical limits and organizational segmentation, bringing together data in a central repository (Olson 2010). DaaS and SaaS have the capacity to present both historical and current states, reporting what happened, why it happened, and what is happening now with regard to both environment and society. From cleaning and consolidating Big Data, analytics-as-a-service (AaaS) shifts the demand from internal manual services to web-delivered technologies, outsourcing the needs from the Internet of things or IoT (Atos 2013) and providing virtual services. AaaS accompanies users throughout their experience, imparting knowledge through artificial intelligence to find expertise and support throughout the entire journey (Takahashi 2017). AaaS and knowledge-as-a-service (KaaS) apply predictive analytics and modelling to interpret Big Data from multiple sources and project the future. Tapping the potential of artificial intelligence could develop strategies not only to foresee future environmental and social challenges, but also to advance solutions by predicting the outcomes of the countries' efforts, responding to the question, how do we make it happen?

The exponential growth of Big Data, technological solutions, complex algorithms and open data sources propels and integrates artificial intelligence into our everyday lives, cities and world networks each year (Herweijer 2018). Artificial intelligence is a powerful tool for countries to navigate in managing environmental concerns and furthering the SDGs, but risks around privacy, biases, declining human intervention and autonomy have to be considered. A road map is needed for how artificial intelligence could transform traditional systems and add value in delivering services, combating the impacts of climate change, building sustainable and liveable cities, and protecting environmental and social welfare. As the scale of economic and health impacts broadens as a result of environmental degradation, strategic measures have to be developed to establish not only human-friendly but also Earth-friendly artificial intelligence.

The new forms of data and knowledge, coupled with conventional tools, will dramatically influence the way solutions are created and delivered. Coping with the shift in the data landscape will need new information technology skills and a holistic approach to utilize emerging and existing data and knowledge tools – thus making data on healthy people and a healthy planet more accessible for environmental assessment and other purposes.

### 25.3.5 Crucial assets of technology

The collection of data in statistical operations follows well-founded methodological approaches, such as sample survey methods and designs. These include well-identified and defined sources, on which systematic methods are applied to transform the data into statistics that lend themselves to time series – the fundamental value of any statistic. New technologies such as remote sensing, transactional data, block chain and artificial intelligence algorithms have the potential to create a wealth of information that is useful for environmental purposes. However, there is a challenge to harness these new technologies to produce time series data, to achieve real-time monitoring and to bring this information into the scope of official statistics.

Only with time series do statistics transform into information, and thereby a fundamental knowledge system. The roles and responsibilities of those who count and those who are counted are also clear cut. The governance of official statistics is predicated on a set of fundamental principles laid down by the United Nations (2014). There are ten principles, including covering the fact that statistical practice should be impartial, should ensure the protection of the privacy of individuals, should be transparent, and should work to ensure the quality of the information produced. Technology has crucial assets which are founded in their development in compliance with standards. Beyond compliance is replication and scaling up. In a way, statistical operations and technological advancement can speed up optimization and give value to visibility, application and transformation of, and from, systems of data, statistics, and can give information to verifiable knowledge systems.

**Figure 25.13: The evolution of the data landscape**

Source: Chartered Property Causality Underliner [CPCU] (2015); ASI Business Solutions (2016).

But are these fundamental principles still relevant in the changed data environment? Maintaining the principles of official statistics involves many challenges in the new data landscape. These include definitional considerations such as concerning the selection of statistical units, data items and their associated spatio-temporal nature. The major paradigm leap for official statistics is how established methodologies of data collection and statistical time series can be adapted in the context of a deluge of unstructured, private (and potentially anonymized) data recorded on electronic devices. Phones, computers and other devices lend themselves readily to standardization and the possibility of replication and scale. For statistics to function optimally, though, standards are needed. Statisticians, technology gurus and data purveyors will need to navigate this space carefully as the hard and laborious slog of carefully designed statistical operations faces a real existential challenge of easy-to-use and fashionable observational tools. Statistics – and its essence, time series – can be greatly challenged in this new environment. The truth is, in the absence of time series, all data can be rendered useless. If a zealous adaptation of technology results in the loss of time series data, it will become impossible to track trends over time. The intersection of technology, data, statistics, knowledge, finance and governance needs to be found.

### 25.3.6 Data assurance and quality practices

With the increasing use of complementary data alongside traditional statistics to support environmental and sustainability policy, questions of how data quality, pedigree and provenance can be assured will need to be systematically answered to determine data that are credible and fit for purpose. Environmental data may come to include digital sources, incorporating Earth observations, citizen science, environmental monitoring, development data and statistics, administrative data sets, and population- and survey-derived data.

In addition to the fundamental principles of statistical practice mentioned above, references and standard practice documents are also emerging for complementary data sources. For example, metadata standards and practices now serve as a basis for data description, including methodological description and data quality. Metadata – the documentation of data – serves the purpose of making data discoverable, usable and understandable. Many discipline-specific or community-specific metadata standards have been developed to support systems of data management and data discovery, and to capture and convey information to users. Examples include directory interchange format (DIF), ecological metadata language (EML), sensor model language (SensorML), climate science modelling language (CSML), and netCDF markup language (NcML). Additionally, the International Organization for Standardization (ISO) has developed a series of standards to describe geographical information – ISO 19115 and ISO 11179.

Data-quality assurance for citizen-science data is in its formative stages, engaging a variety of digital-platform techniques for quality checking field observations contributed by citizens. Examples include the Local Environmental Observer (LEO) Network in the North American Arctic region, using a smartphone app that uploads observations for expert checks before being used in graphic displays on maps and

in tabular data sets (LEO Network 2017). Recent workshops convened by the European Commission's Joint Research Centre are also beginning the process of establishing principles for mobile apps and platforms.

The Group on Earth Observations has propagated its Global Earth Observation System of Systems (GEOSS) data management principles, which are being widely adopted by Earth Observation entities (Group on Earth Observations 2014). Included in the coverage of the principles are: discoverability, accessibility, usability, preservation and curation.

As open-source analytics, community-sourced query codes and custom data-integration methods advance, there will be more community curation of data sets, exchange standards and application-programming interfaces. Code sets incorporating analytics and queries are now routinely community-curated on open collaboration platforms such as the GitHub development platform.

The Research Data Alliance sets registry standards for long-term curation and for defining the parameters of data sets in Earth science and other research domains. Complementary data sources will be judged to be credible as far as they conform with these registry standards.

The ultimate test for the data revolution of open and accessible digital data will be user satisfaction and integrated platform requirements for aligning with an array of recognized standards, practices and open source community-driven testing for methodology and data quality from across environmental, natural resource and development data.

## 25.4 Conclusion: Challenges, gaps and opportunities

The challenges, gaps and opportunities related to environmental data and statistics are presented below. Data and knowledge are valuable assets that need to be shared.

### 25.4.1 Data disaggregation

The SDGs call for a data revolution that leaves no one behind, incorporating disaggregated data and reporting at all levels of the 17 goals. As highlighted in Chapter 3 of this report, assessing the nexus between society and the environment can be done only if there is disaggregated information on different populations because not all people have the same level of dependence on the environment, nor the same impact on it. To tease out these differences, then, there is a need for information that can be disaggregated by income, gender, age, ethnicity, migratory status, disability, geographical location and other characteristics relevant in national contexts. Unfortunately, there is currently a dearth of environment-related information that can be disaggregated, and data from household surveys on access to water, energy and other natural resources is available only at the household level, which makes understanding differences at other levels difficult.

In addition to disaggregation by socioeconomic variables there is also a need for geospatial disaggregation of environmental information. Biological ecosystems do not follow national boundaries, so to understand both the state of particular ecosystems and the interactions between them and people

and the economy requires spatially disaggregated information. Disaggregation will require bringing together Earth observation data, data from traditional censuses and surveys, as well as citizen science, traditional knowledge and Big Data into an integrated data ecosystem.

#### 25.4.2 Open data access

Many developing countries will need access to unrestricted open data. In terms of data governance, the overall management of the availability, usability, integrity and security of the data should be made transparent. The continental leaders of vast, validated data sets – North America and Europe – are currently the data stewards making their valuable resources readily available to the rest of the world as public goods. What may be needed is a sound data-governance programme that includes a governing body or council and a defined set of procedures, with a plan for their execution. Governments should ensure that there are legal frameworks in place to promote good data governance. A documented, transparent data-governance policy will establish a set of easy-to-follow guidelines for ensuring the proper management of information, helping to answer questions revolving around sovereignty, security, data quality and privacy. In particular, protecting the privacy of individual people is an essential component of data governance. To help shepherd this governance programme, multilateral data stewards, responsible for the management and fitness of data elements, should be assigned to ensure that data exchanges are executed precisely and consistently between computer systems and between different collection methods (see 'Institutional arrangements' below).

#### 25.4.3 Data and information governance

Governance of data involves managing and leveraging all data assets (dispersed among large external open data sources, central databases, and other existing and emerging data and knowledge sources from governments, institutions, research, and studies). Information technology alone is insufficient to draw full value from the exponential growth of potential data assets. Policy makers generally lack an understanding of the distinct issues that information technology has to deal with, and the need for active organizational involvement and institutional ownership. Addressing the challenges posed by Big Data means the integration of valuable information through a combined process of 'data semantics' and the intervention of a data-governance specialist.

Dealing with Big Data involves the storage of all data resources, sorting them out and identifying which data make sense beyond local use, and accessing the disparate data and finding their relationships. Having the right tools is not enough to sift through Big Data and find any relevant patterns and relationships. Like any valuable asset, information needs to be managed and secured through careful practices of

designing, creating, developing and deploying data. With proper governance, the meaning, use and integrity of the data are preserved over time, increasing the value of data as an asset.

#### 25.4.4 Public-private partnerships

The challenges of scarce resources and lack of financial capability in progressing the use of big-data analytics, particularly in developing countries, could be helped through public-private partnerships. The public sector could exercise the social implementation of big-data analytics as private entities finance and build on the technical know-how (Groff 2017). Public-private projects provide opportunities to strengthen statistical and information systems, develop innovative data-collection methods and initiate co-creation through people-first partnerships. Partnerships between the government and the private sector that involve civil society may result in the adoption of best practices in data collection, analytical assessment and monitoring for SDG-related information.

#### 25.4.5 Institutional arrangements

The institutional arrangements between different authorities and agencies producing and holding environmental information are in their early stages (e.g. official statistics, map-based information on natural resources, hydrometeorological, geospatial monitoring, environmental and geospatial portals, open-data governmental portals, etc.). Any future measures should aim to improve institutional arrangements to facilitate the effective integration, sharing and reuse of data across barriers, including those of sovereignty, mandates, bureaucracy, knowledge gaps, standards and standardization, digitization and digitalization. These challenges need to be resolved. Open data and instruments that facilitate its use, such as the Statistical Data and Metadata eXchange (SDMX), hold promise for seamless data sharing. However, many countries face challenges in terms of implementing open-data instruments. National governments need to commit to common global goods, and intergovernmental arrangements are necessary to facilitate solutions to some of the political problems arising from government limitations.

#### 25.4.6 Capacity-building

Sustainable capacity is achieved when the entire value chain works – where data from collation and analysis through to use are dealt with competently to deliver the value of the information, disseminate it through the most effective and efficient channels, and ensure that those for whom its value is intended are able to use it. To reach this stage of competency, environmental education should be implemented at all levels. Indigenous knowledge systems, including emerging opportunities offered by technological advances to democratize the participation of citizens in the exercise of science and scientific discovery should be facilitated.

#### 25.4.7 Traditional knowledge

The challenge around the continued use and development of traditional knowledge is the lack of effective implementation of rights to indigenous knowledge, resulting in the loss of lands and the misappropriation of traditional knowledge. The inclusion of traditional knowledge does not guarantee the equality of benefit sharing.

The opportunities for traditional knowledge to contribute to sustainable development include the improved effort in documenting traditional knowledge and the increasing network building partnerships to develop innovative tools and methodologies for a better understanding of traditional knowledge to be used in strategic plans and interventions and to assess changes in ecosystems. The commitment of UN member states for sustainable development also matters when discussing traditional knowledge.

#### 25.4.8 Integrated data systems

The physical and social systems, hand in hand, comprise the real state of the environment. Without both, the picture of where we are now and where we are heading would be incomplete. A combination of conventional methods with

emerging forms of data and knowledge, and with the social data, could provide a holistic view of the environment, encompassing social, physical and economic perspectives.

Societies often notice change before measurable environmental change occurs – but, we also need to look into how data, information and knowledge are used and understood. In the era of information technology, the problem may not be the lack of knowledge or data on what is happening, but rather on the question of which available data should be acted on, what kind of information, based on which assumptions, is considered legitimate, and which reality counts (Davies 1994).

A shift in thought processes on environmental assessments would bring data, including from Big Data, citizen science and traditional knowledge to the forefront with Earth observation and official statistics. This would allow the environmental challenges to be identified, the progress in addressing the SDGs to be monitored, and the solutions to be drafted for sound and evidence-based policy-making. This would require not only turning the challenges of environmental data into opportunities, but also improving data integration, utilizing both existing and emerging tools for environmental assessment, and making data openly available for use.

## Annexes

## Annex 1-1: Mission of the sixth Global Environment Outlook

Within UN Environment's mandate to keep the environment under review, Member States have requested that UN Environment continue to review the environmental dimension of the SDGs, which are at the core of the 2030 Agenda for Sustainable Development (United Nations 2015a). GEO-6 is a powerful tool to strengthen UN Environment's role within the science-policy interface with multiple functions:

- ❖ Support UN Environment's pivotal role in providing assessments, policy analysis, integrative analytics, and approaches to deliver on the environmental dimension of the SDGs, including the follow-up and review process;
- ❖ Be UN Environment's instrument to support member states, major groups, stakeholders, and UN system entities' implementation of the 2030 Agenda through the UN System-wide Strategies on the Environment adopted in 2016;
- ❖ Help UN Environment align its strategic planning to the 2030 Agenda and strengthen collaboration with the rest of the UN system, and in doing so, embed the environment in global normative frameworks, and address emerging environmental issues (UNEP 2016d).

The GEO-6 assessment also supports UN Environment's core principles on delivering the environmental dimension of the 2030 Agenda, including the principles of:

- a. Universality [all people – beyond borders – collective action]: The 2030 Agenda is global, applying to all people in all countries. It is a shared agenda that requires a collective response from the international community, governments, businesses and citizens' groups.
- b. Human rights and equity [pathway to a fair, just and sustainable world]: The 2030 Agenda encourages a more-even distribution of wealth and resources, equitable access to opportunities, information and the rule of law; including the development of new approaches that build capacities at all levels of society.

- c. Integration [acting as a harmonious whole]: Past approaches treated the social, environmental and economic dimensions of sustainable development as disconnected pillars, but the new agenda integrates and balances all three.
- d. Innovation [invention is the master key to progress]: The acceleration and transfer of technological innovations is key to delivering the 2030 Agenda. The world will need new innovation pathways that draw on formal science, traditional knowledge and citizens' common sense (UNEP 2015b).

Compared with previous GEOs, the sixth edition provides the first integrative baseline in light of global megatrends supported by various sources of open and accessible data and information, and a pluralistic knowledge base, with due consideration given to gender and youth, indigenous knowledge, and cultural dimensions. Also new in this edition is the integration and discussion of economic aspects of sustainable development and the dimension of social equity throughout the assessment, not only to strengthen overall policy relevance, but also to highlight that environmental change and degradation cause tremendous pressure on global economic prosperity, social justice and overall human well-being. GEO-6 also reflects on the impact of economic prosperity and social justice on environmental degradation.

The GEO process laid the foundation for continued and intensified socio-economic-environmental assessment across relevant scales, with a thematic as well as an integrative focus, enabling and informing societal transitions and the tracking of SDG goals and targets, as well as previously internationally agreed environmental goals. Therefore, GEO-6 aims to assist Member States, international organizations, and Major Groups (like non-governmental organizations) to position themselves on the most effective pathway for transitions towards a sustainable future over various time frames (2030/2050), considering the extensive inter-dependencies between the environment and people's well-being (e.g. Healthy Planet, Health People).

## Annex 1-2: Range of integrated environmental assessments which the sixth Global Environment Outlook draws from

GEO-6 draws and integrates findings from major global environmental assessments, including IPCC, IPBES, etc.

**Table A.1: Examples of Global Environmental Assessments and their links to GEO-6**

| Assessment                                                                     | Lead Organization                                           | link                                                                                                                                                                                                                                      | Objectives                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | Links to GEO-6                                                                                                                                                                                                             |

| Global Biodiversity Outlook (GBO) IV                                           | Convention on Biological Diversity (CBD)                    | <a href="https://www.cbd.int/gbo4/">https://www.cbd.int/gbo4/</a>                                                                                                                                                                         | To periodically assess and summarize the latest data on the state of biodiversity and draw conclusions relevant to the further implementation of the Convention.                                                                                                                                                                                                                                                                                                                                                                                 | Used as a key reference in the thematic chapter on biodiversity, including policy responses and outlooks.                                                                                                                  |
| World Water Assessment Programme (WWAP)                                        | UNESCO, UN-Inter-agency (UN-Water)                          | <a href="http://www.unesco.org/new/en/natural-sciences/environment/water/wwap">http://www.unesco.org/new/en/natural-sciences/environment/water/wwap</a>                                                                                   | Comprehensive review that gives an overall picture of the state of the world's freshwater resources and aims to provide decision-makers with the tools to implement sustainable use of water resources.<br><br>To provide a mechanism for monitoring changes in the resource and its management, while tracking progress towards achieving targets, particularly those of the MDGs/SDGs.<br><br>To offer best practices as well as in-depth theoretical analyses to help stimulate ideas and actions for better stewardship in the water sector. | Reports within the WWAP and their results served as a baseline for the thematic chapter on freshwater, and related cross-cutting issues, including policy responses and outlooks.                                          |
| World Ocean Assessment I (2015)                                                | Group of Experts of the Regular Process/UN General Assembly | <a href="http://www.worldoceanassessment.org/">http://www.worldoceanassessment.org/</a>                                                                                                                                                   | The global mechanism for reviewing the state of the marine environment, including socioeconomic aspects, on a continual basis by providing regular assessments at the global and supranational levels and an integrated view of environmental, economic and social aspects.                                                                                                                                                                                                                                                                      | Results of the World Ocean Assessment I served as a baseline for the thematic chapter on oceans and coasts and relevant cross-cutting issues, including policy response and outlooks.                                      |
| Global Land Degradation Assessment/Global Soil Health Assessment (2015)        | FAO, UNEP                                                   | <a href="http://www.fao.org/soils-portal/soil-degradation-restoration/global-soil-health-indicators-and-assessment/jp/">http://www.fao.org/soils-portal/soil-degradation-restoration/global-soil-health-indicators-and-assessment/jp/</a> | To provide a global scientific assessment of current and projected soil conditions built on regional data analysis and expertise; to explore the implications of these soil conditions for food security, climate change, water quality and quantity, biodiversity, and human health and wellbeing; and to conclude with a series of recommendations for action by policymakers and other stakeholders.                                                                                                                                          | Results of these assessments served as a baseline for the thematic chapter on land and relevant cross-cutting issues, like food security, including policy responses and outlooks.                                         |

| Assessment                                          | Lead Organization                                         | link                                                                                                                                                                                                                            | Objectives                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | Links to GEO-6                                                                                                                                                                                                                                                                                                                         |
|-----------------------------------------------------|-----------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Global Land Outlook (GLO) (2017)                    | UNCCD                                                     | <a href="http://www2.unccd.int/publications/global-land-outlook">http://www2.unccd.int/publications/global-land-outlook</a>                                                                                                     | The GLO presents an overview of the status of land and a clear set of responses to optimize land use, management, and planning, and thereby create synergies across sectors in the provision of land-based goods and services. This integrated approach is the basis of the conceptual framework for land degradation neutrality, a target which is seen as the driving vehicle for the implementation of the United Nations Convention to Combat Desertification (UNCCD) and an important part of the 2030 Agenda for Sustainable Development. | Results of the GLO were used for the thematic chapter on land and soil and relevant cross-cutting issues, like food security, including policy responses and outlooks.                                                                                                                                                                 |
| Global Waste Management Outlook (2015)              | UNEP, International Association of Solid Waste Management | <a href="http://www.unep.org/ourplanet/september-2015/unep-publications/global-waste-management-outlook">http://www.unep.org/ourplanet/september-2015/unep-publications/global-waste-management-outlook</a>                     | To assess the global state of waste management. Develop a holistic approach towards waste management and recognizing waste and resource management as a significant contributor to sustainable development and climate change mitigation. To complement the Sustainable Development Goals of the Post-2015 Development Agenda/SDGs, the Outlook sets forth Global Waste Management Goals and a Global Call to Action to achieve those goals.                                                                                                    | Results of the Global Waste Management Outlook were used as a core reference to address key challenges of waste and resource management as cross-cutting issues within GEO-6, including policy responses and outlooks                                                                                                                  |
| Global Chemicals Outlook I                          | UNEP                                                      | <a href="http://www.unep.org/chemicalsandwaste/what-we-do/policy-and-governance/global-chemicals-outlook">http://www.unep.org/chemicalsandwaste/what-we-do/policy-and-governance/global-chemicals-outlook</a>                   | Develop a comprehensive environmental understanding and up to date assessment of the trends and changes affecting the production and use of chemicals, their health and environmental effects, economic implications, and policy options throughout their life cycle. The GCO I is meant to be informative so as to illustrate both the economic interest and the necessity to invest in the sound management of chemicals.                                                                                                                     | Results of the Global Chemicals Outlook I were used as core reference to address key challenges of chemicals as cross-cutting issues within GEO-6, including policy responses and outlooks                                                                                                                                             |
| Global Mercury Assessment (2002/2008/2013/2018)     | UNEP                                                      | <a href="http://web.unep.org/chemicalsandwaste/what-we-do/technology-and-metals/mercury/global-mercury-assessment">http://web.unep.org/chemicalsandwaste/what-we-do/technology-and-metals/mercury/global-mercury-assessment</a> | The Global Mercury Assessment provides the most recent information available for the worldwide emissions, releases, and transport of mercury in atmospheric and aquatic environments. The Global Mercury Assessment is intended as a basis for decision making, emphasis is given to anthropogenic emissions (mercury going into the atmosphere) and releases (mercury going into water and land), that is, those associated with human activities.                                                                                             | Results of the latest Global Mercury Assessment (2013/2018) were used as reference within the air thematic chapter, the cross-cutting theme of chemicals, including policy responses and outlooks.                                                                                                                                     |
| Global Gender and Environment Outlook (GGEO) (2016) | UNEP                                                      | <a href="http://web.unep.org/ggeo">http://web.unep.org/ggeo</a>                                                                                                                                                                 | The GGEO for the first time provides a comprehensive global overview of the linkages between gender and environment in the contexts of SDGs and 2030 Development agenda. Its objectives are to enable better understanding of the environment through a gender lens, to support better integration of gender perspectives in development and implementation of environmental policies at international and national levels, and to drive impact through partnerships.                                                                           | For chapter 4 and 17 on Cross-cutting issues the GGEO has been instrumental as a basis for the gender-related language. As the GGEO is specifically looking into gender aspects of diverse environmental areas, policies, data and approaches, the insights of GGEO are also integrated into several other GEO6 chapters and sections. |

## Annex 1-3: Theory of Change for the sixth Global Environment Outlook (GEO-6)

Based on the principles of integrated environmental assessments, the theory of change in GEO-6 is embedded in its structure and purpose and based on a social process that moves a community of institutions and people towards a new way of (strategic) thinking and (goal-oriented) acting. Through this social process, the evidence presented in the GEO-6 assessment is considered legitimate, credible and relevant (salient) to the community, which facilitates its acceptance as an input to improved environmental policy, which in turn helps make progress towards sustainable development.

GEO-6 aims to create change through a process that encompasses data, science and experimental and participatory approaches. It uses multidisciplinary perspectives to generate knowledge-based conclusions. GEO-6 also aims to create change by highlighting the benefits and opportunities to citizens and communities from achieving change, even disruptive change. New earth observation and other technologies have revolutionized our ability to understand environmental change and its impacts on human well-being and vice versa. GEO-6 aims to communicate the results of the assessment in a way that can influence action by stakeholders and policymakers. This, in turn, facilitates the development of more appropriate, equitable, and effective policy responses,

including shifting investment, production, distribution, and consumption in more sustainable directions, as well as better governance capacities at multiple scales.

**Figure A.1** shows how GEO has impacts through its influence on people's actions:

### Activities and process

The Global Environment Outlook process is designed through consultations with governments and other stakeholders. From these consultations, nominations of government officials, stakeholders and experts who will be involved in the process create the community that will follow, and be influenced by the process. Regular meetings and conference calls are necessary to keep this community engaged in the process and also to obtain their advice so that they feel ownership of the process and the product. Peer review and intergovernmental review processes allow a broader community of experts, governmental officials and stakeholders to contribute their advice and expertise and experience a higher level of engagement. The community members, motivated by a sense of ownership through their participation in the process, become ambassadors for GEO's messages.

**Figure A.1: Theory of Change of GEO-6**

## Outputs

The four main outputs of the GEO process document the evidence and rationale for the findings that will influence the future path of environmental and sustainable development policy. These outputs include:

- ❖ Six regional environmental assessments which present policy relevant information which is actionable either regionally and/or nationally. These regional assessments allow for a deeper ownership of the findings at a level where governments can act. They also engage different geographic groupings in the process of implementing GEO's findings;
- ❖ Following the publication of the regional assessments, a global environmental assessment is produced, which can look at broader issues, such as the state of the world's environment, presenting the findings at a level where governments, together, can act.
- ❖ One of the main equity issues related to environmental analysis is how environmental impacts and actions are differentiated by gender. For this reason, there is a systemic link with the Global Gender and Environment Outlook.
- ❖ The findings and new knowledge of GEO should be translated and disseminated through the production of teaching and outreach material to stimulate further capacity building. Capacity building makes GEO accessible to a much broader audience such as youth and educators and enables its findings and new recommended directions to be promoted more widely, thereby enhancing GEO's influence on environmental change over a longer period and strengthening the long-term durability of these changes.

## Drivers, Assumptions and Risks

A main assumption of the assessment process is that the findings will be considered legitimate, scientifically credible and relevant by the intended audiences, especially governments. These three criteria are defined as:

- ❖ Legitimacy: considered unbiased and respecting different stakeholder perspectives and conforming to law or authoritative rules.
- ❖ Credibility: considered scientifically sound and authoritative. Producing information that can be believed and trusted.
- ❖ Relevant: considered timely and related to the needs of the end users.

The GEO achieves legitimacy, credibility, and relevance through several avenues, based on certain assumptions, and subject to some risks, including:

- ❖ A clear mandate is provided by governments to produce the GEO and governments help to define some of the key parameters, such as the timeframe, organizational structure, work plan, outline for the analysis, etc.
- ❖ Sufficient funding is made available, following a clear work plan which is developed and approved by the Secretariat, in consultation with appropriate advisory bodies that are part of the process.

- ❖ A sufficiently large and diverse cohort of authors and experts is engaged to produce the report such that they ensure the scientific credibility of the assessment and can devote the appropriate amount of time to the analysis and drafting of chapters during the approved period of the work programme. This includes peer reviewers and other experts working outside the main drafting process.
- ❖ A robust process for negotiating related products meant for policy makers (e.g. Summary for Policymakers) is undertaken, which is transparent and considers the views of all Member States. These products help increase the legitimacy of the assessment process and, with appropriate endorsement, can lend credibility to these products.

## Outcomes

The outcomes of the GEO process focus on increased awareness of the current state of the environment, knowledge of the possible policy solutions that could be used to address these, including the future implications of not acting and the future benefits of following particular pathways to achieve environmental goals. In order to achieve these goals, the findings of the assessment must be understood and/or used by various actors and applied in their daily work and personal lives:

- ❖ Policy analysts must access and understand GEO's findings, using them appropriately to inform decision makers;
- ❖ More broadly, governments (and potentially other non-state actors) should understand the findings in order to use them to advance their policy work. Governments can also use the GEO methodology to prepare their own regional, national or sub-national assessments if desirable.
- ❖ United Nations and other international organizations should be able to understand and apply GEO's findings in their own assessment, policy work, and practice.
- ❖ Civil society and non-governmental organizations should be able to understand and apply the findings of GEO in their own work, e.g. by influencing the policy and decision-making processes on the environment.

## Impact

The impact of the GEO will be judged by the responses and actions that governments, institutions, and people take in their work arenas and daily lives. To increase the impact of GEO, UN Environment facilitates actions in the following areas:

- ❖ Helping countries strengthen the science-policy interface through the promotion of the GEO findings and process;
- ❖ Promoting the use of evidence-based decision making based on the findings of the GEO, its various derivative products, and other scientific sources;
- ❖ Encouraging, directly and indirectly, changes at the regional and national policy level that are in line with the GEO reports and process.

The theory of change for GEO supports various actors, including national governments, to make progress towards achieving the Sustainable Development Goals. This can be facilitated by incorporating the findings of the GEO into the Agenda 2030 policy process and implementation.

## Annex 1-4: Structure and rationale for confidence statements used in the sixth Global Environment Outlook

### Guidance from the Scientific Advisory Panel

This document is adapted from guidance developed by the Intergovernmental Science-Policy Platform on Biodiversity and Ecosystem Services (IPBES), IPBES/5/INF/6.

### Developing and applying confidence terms

Characterizing and communicating the confidence and uncertainty in findings is essential to ensure the scientific credibility of the assessment process, help stakeholders and decision-makers understand the strength and weight of the underlying evidence base and lead to more informed decision-making. This guidance note is intended to assist authors of the Global Environment Outlook (GEO-6) to describe, in a consistent and transparent manner, the confidence and uncertainty associated with their findings. The note suggests a common approach and calibrated language that can be used broadly for developing expert judgments and for evaluating and communicating the degree of certainty.

### What is confidence?

The use of confidence statements in assessments reflects how assured authors are about the findings (data and information) presented within their chapters. Low confidence describes a situation where we have incomplete knowledge and therefore cannot fully explain an outcome or reliably predict a future outcome, whereas high confidence conveys that we have extensive knowledge and are able to explain an outcome or predict a future outcome with much greater certainty.

Confidence terms should always be used in three key parts of an assessment:

1. They should be assigned to the key findings in **Executive Summaries** of the technical chapters in an assessment report.
2. They should be used for the key findings in any **Technical Summary** produced from the main report.
3. They should be used within the **Summary for Policymakers**.

It is not mandatory to apply confidence terms throughout the main text of the assessment report. However, in some parts of the main text, in areas where there are a range of views that need to be described, confidence terms may be applied where considered appropriate by the author team. In no case should the terms be used colloquially or casually to avoid confusing readers. Only use these terms if you have followed the recommended steps for assessing confidence.

### Assessing confidence

As they develop their key findings, author teams should evaluate the associated evidence and agreement within the evidence base. Depending on the nature of the evidence evaluated, teams may either use a qualitative level of confidence or quantify the uncertainty in the finding probabilistically. Qualitative assessments of confidence reflect expert judgment about agreement and evidence. Quantitative assessments of confidence are estimates of the likelihood (probability) that a well-defined outcome will occur in the

future. Probabilistic estimates are based on statistical analysis of observations or model results, or both, combined with expert judgment. However, it may be that quantitative assessments of confidence are not possible for all findings due to the nature of the evidence available.

In order to ensure consistency in communication, specific phrases or terms will be used to describe the level of confidence or the extent of uncertainty. The choice of the term used will be based on the author team's expert judgement on the quantity and quality of the supporting evidence and the level of scientific agreement.

The sixth Global Environment Outlook uses a four-box model of confidence (see **Figure A.2**) based on evidence and agreement that gives four main confidence terms for the qualitative assessment of confidence: "well established" (much evidence and high agreement), "unresolved" (much evidence but low agreement), "established but incomplete" (limited evidence but good agreement) and "inconclusive" (limited or no evidence and little agreement).

### Qualitative assessment of confidence

This section discusses the process and language that all author teams must apply to evaluate and communicate confidence qualitatively. The following factors should be considered while assessing the confidence in a message or finding: the type, quantity, quality and consistency of evidence (the existing peer-reviewed literature and grey literature etc.), and the level of agreement (the level of concurrence in the data, literature and amongst experts, not just across the author team). The author team's expert judgement on the level

**Figure A.2: The four-box model for the qualitative communication of confidence**

Confidence increases towards the top-right corner as suggested by the increasing strength of shading.

Source: IPBES (2017).

of evidence and agreement should then be used to apply a confidence term (**Figure A.2**):

- ❖ **Inconclusive** – existing as or based on a suggestion or speculation; no or limited evidence and no clear consensus in the evidence.
- ❖ **Unresolved** – multiple independent studies exist but conclusions do not agree.
- ❖ **Established but incomplete** – general agreement although only a limited number of studies exist but no comprehensive synthesis and, or the studies that exist imprecisely address the question.
- ❖ **Well established** – comprehensive meta-analysis or other synthesis or multiple independent studies that agree.

The **well-established** box in **Figure A.2** can be further subdivided in order to give author teams the flexibility to emphasise key messages and findings that the author team have very high confidence in:

- ❖ **Very well established** – very comprehensive evidence base and very low amount of disagreement.
- ❖ **Virtually certain** – very robust evidence base covering multiple temporal and spatial scales and almost no disagreement.

Note that the term “virtually certain” above still reflects a qualitative assessment of confidence. It should not be interpreted probabilistically and does not convey any level of “statistical significance”. These sub-classifications of the “well established” box provide authors flexibility to emphasize findings that may be considered as fact or reflecting scientific consensus.

The degree of confidence in findings that are conditional on other findings should be evaluated and reported separately.

When evaluating the level of evidence and agreement for a statement, it is important to standardise the use of the terms within and across the author teams, and when possible, across the assessment, to ensure their consistent use. The use of the above confidence terms can be standardised by taking key messages and findings in the **Executive Summaries** and discussing, as an author team, what terms should be applied and the reasons why. When appropriate, teams may consider using formal elicitation methods to organise and quantify the selection of confidence terms.

Teams should be aware of the tendency for a group to converge on an expressed view and become over confident in it. One method to avoid this would be to ask each member of the author team to write down his or her individual assessment of the level of confidence before entering into a group discussion. If this is not done before group discussion, important views and ranges of confidence may be inadequately discussed and assessed. It is important to recognize when individual views are adjusting as a result of group interactions and allow adequate time for such changes in viewpoint to be reviewed (Mastrandrea *et al.* 2010). Whichever approach is taken, traceable accounts should be produced and recorded to demonstrate how confidence was evaluated (see section on Traceability).

It is important to carefully consider how the sentences in the key messages and findings are structured because it

will influence the clarity with which we communicate our understanding of the level of confidence. For example, sometimes the key finding combines an element that is **well-established** with one that is **established but incomplete**. In this case it can be helpful to arrange the phrasing so that the **well-established** element comes first, and the **established but incomplete** element comes second, or as a separate sentence. Where possible avoid the use of the **unresolved** and **established but incomplete** by writing or rewording key messages and findings in terms of what is known rather than unknown. Author teams should focus on presenting what is **well-established** as far as possible in order to make it clear to decision makers what is known. Assigning confidence terms to our key findings will therefore often require that we re-write sentences, rather than simply adding the terms to existing text.

## Quantitative assessment of confidence

In many cases it may be possible to quantitatively assess the uncertainty in an outcome or event. This section discusses the process and language that author teams may wish to apply in order to evaluate and communicate the confidence that an outcome will occur quantitatively. Likelihood expresses a probabilistic estimate of the occurrence of a single event or of an outcome within a given range. Probabilistic estimates are based on statistical analysis of observations or model results, or both, combined with expert judgment.

When sufficient probabilistic information is available, consider ranges of outcomes and their associated probabilities with attention to outcomes of potential high consequence. The author team’s expert judgement on the magnitude of the probability should then be used to apply a likelihood term from **Figure A.3**.

**Figure A.3: Likelihood scale for the quantitative communication of the probability of an outcome occurring**

Note that the extreme levels of probability are nested within the broader levels of “likely” and “unlikely”.

Source: Adapted from Mastrandrea *et al.* (2010).

Categories in **Figure A.3** can be considered to have nested boundaries. For example, describing an outcome as **likely** or **very likely** conveys in both cases that the probability of this outcome could fall within the range of 95 per cent to 100 per cent probability, but in the case of **likely**, the larger range (66-100 per cent) indicates a higher degree of confidence than **very likely** (90-100 per cent). In making their expert judgement, author teams should start at **about as likely as not** and consider whether there is sufficient quantitative information available to assign either a **likely** or **unlikely** probability range. Only after thinking about this initial range should the author teams consider whether there is sufficient evidence to move to more extreme levels of probability.

Author teams should note that using a likelihood term for a specific outcome implies that alternative outcomes have the inverse likelihood e.g., if an outcome is **likely** (a range of 66-100 per cent) than that would imply that other outcomes are **unlikely** (0-33 per cent probability).

If the author team consider that sufficiently robust information is available with which to make a 'best estimate' of the probability of the occurrence of an event, then it is preferable to specify the full probability range (e.g. 90-95 per cent) in the text without using the terms in **Figure A.3**. Also, **about as likely as not** should not be used to communicate a lack of knowledge, only an estimate of probability based on the available information.

Author teams should be aware of the way in which key messages and findings are phrased. The way in which a statement is framed will have an effect on how it is interpreted e.g., a 10 per cent chance of dying is interpreted more negatively than a 90 per cent chance of surviving. Consider reciprocal statements to avoid value-laden interpretations e.g., report chances both of dying and of surviving (Mastrandrea *et al.* 2010).

Finally, author teams should try not to avoid controversial events, such as impacts or events with high consequence but extremely low probability, in their effort to achieve consensus within an author team.

### How to present confidence terms - Presenting confidence using the four-box model

Confidence terms are communicated as part of the key findings of an assessment. The key findings are set out in the **Executive Summaries** for each of the assessment's chapters in the full technical report. The key findings are the facts and information drawn directly from the chapter. It is recommended that key findings should be set out as follows.

**The first sentence of the finding should be bolded** and contain a confidence term from the four-box model in italics and brackets at the end of the sentence. This first sentence is followed by two to four sentences which then supports the information contained in this first sentence. Subsequent sentences may contain confidence terms within brackets where appropriate. It is not necessary to include confidence terms with each sentence if the whole paragraph falls under the same confidence term.

The words that make up the four-box model and likelihood scale should not be used in the text of the assessment except when formally assigning confidence. If, for example, there was a sentence that used the word "likely" but not with the intended

meaning from the likelihood scale, then the word should be replaced with another (e.g. probably).

### Presenting confidence using the likelihood scale

In some instances, as above, author teams may wish to complement the use of the **well-established** confidence term with a term from the likelihood scale. If terms from the likelihood scale are used then they should be incorporated into the text and italicised prior to the impact or outcome the probability of which they are describing.

### Traceability

The author team's expert judgment of their confidence in the key messages and findings should be explained by providing a clear traceable account. A traceable account is a description in the chapter of the evaluation of the type, quantity, quality and consistency of the evidence and level of agreement that forms the basis for the given key message or finding (Mastrandrea *et al.* 2010). Where possible, the description should identify and discuss the sources of confidence. In order to ensure consistency in how the author teams classify sources of confidence within and across Global Environment Outlook assessments, author teams should use the typology shown in **Table A.2** below.

A key statement in the **Summary for Policymakers** should be readily traceable back to an **Executive Summary** statement(s) that in turn should be readily traceable back to a section(s) of the chapter text, which in turn should be traceable where appropriate to the primary literature through references.

References to the relevant **Executive Summary** statement should be included in curly brackets (e.g. {1.2}).

### Summary of Steps for applying confidence terms

The steps recommended for assessing and communicating confidence for Executive Summaries and Summaries for Policymakers.

1. Identify the chapter's key messages and findings.
2. Evaluate the supporting evidence and the level of scientific agreement.
3. Establish whether the evidence is probabilistic or not (e.g. from model predictions).
4. Where the evidence is qualitative instead or probabilistic, select a confidence term from the four-box model (**Figure A.2**) to communicate the author team's confidence in the key message or finding.
  - (a) Assess the quantity and quality of evidence and the level of agreement in the scientific community.
  - (b) Establish how confident the author team is and select the appropriate term.
5. Where quantitative estimates of the probability of an outcome or impact occurring are available (e.g. from model predictions), select a likelihood term from the likelihood scale (**Figure A.3**) to communicate the author teams' expert judgement of the range of the probability of occurrence.
6. Ensure that there is always a 'traceable account' in the main text describing how the author team adopted the specific level of confidence, including the important lines of evidence used, standard of evidence applied and approaches to combine/reconcile multiple lines of evidence.
7. OPTIONAL: Consider using formal frameworks for assessing expert judgement for each author team.

**Table A.2: Sources of low confidence**

| Sources of low confidence                                           | Definition and examples                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | Qualities                               | Means of dealing with low confidence                                                                                                                                                                                                                                                                                                                                                               |
|---------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Imprecise meanings of words<br>(Linguistic uncertainty)             | Vagueness and ambiguity of terms<br>EXAMPLE: When terms such as human welfare, risks, plant reproductive success, pollination deficits are central to the finding.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | Reducible<br>Not quantifiable           | <ul style="list-style-type: none"> <li>❖ Clear, common definition of terms (IPBES Common Glossary).</li> <li>❖ Protocols as used in agent-based modelling to deal with context dependence.</li> </ul>                                                                                                                                                                                              |
| Inherently unpredictable systems<br>(Stochastic uncertainty)        | Low confidence due to the chaotic nature of complex natural, social or economic systems (sometimes known as 'aleatory' uncertainty). Findings that depend on weather or climate variables, or market prices, will be subject to this low confidence.<br>EXAMPLE: Pollination deficits and values measured at local scales.                                                                                                                                                                                                                                                                                                                                                                                                | Not reducible<br>Quantifiable           | <ul style="list-style-type: none"> <li>❖ Clear communication.</li> <li>❖ Using probabilistic approaches.</li> <li>❖ Support large scale, long term multi-site studies to quantify the variation over space and time to characterise the low confidence.</li> <li>❖ Evidence synthesis.</li> <li>❖ Capacity building for researchers and decision makers.</li> </ul>                                |
| Limits of methods and data<br>(Scientific uncertainty)              | Where there is insufficient data to fully answer the question, due to unsatisfactory methods, statistical tools, experimental design or data quality (also referred to as epistemic uncertainty).<br>EXAMPLE: Impacts of pesticides on pollinator populations in the field, trends in pollinator abundance, estimations of ecosystem service delivery.                                                                                                                                                                                                                                                                                                                                                                    | Reducible<br>Quantifiable               | <ul style="list-style-type: none"> <li>❖ Acknowledge differences in conceptual frameworks (within and between knowledge systems).</li> <li>❖ Improve experimental design.</li> <li>❖ Expand data collection.</li> <li>❖ Support detailed, methodological research.</li> <li>❖ Knowledge quality assessment.</li> <li>❖ Evidence synthesis.</li> <li>❖ Capacity building for scientists.</li> </ul> |
| Differences in understanding of the world<br>(Decision uncertainty) | Low confidence that is caused by variation in subjective human judgments, beliefs, world views and conceptual frameworks (sometimes called epistemic uncertainty). In terms of policy decisions, low confidence is due to preferences and attitudes that may vary with social and political contexts. This can mean a finding looks different in different knowledge systems that cannot easily be aligned.<br>EXAMPLES: Effects of organic farming look different if you take the view that wild nature beyond farmland has a higher value than farmland biodiversity, and overall food production at a large scale is more important than local impacts. There are divergent interpretations/perceptions of well-being. | Sometimes reducible<br>Not quantifiable | <ul style="list-style-type: none"> <li>❖ Acknowledge differences in conceptual frameworks (within and between knowledge systems).</li> <li>❖ Document, map and integrate where possible.</li> <li>❖ Acknowledge existence of biases.</li> <li>❖ Multi-criteria analysis, decision support tools.</li> <li>❖ Capacity building for decision makers.</li> </ul>                                      |

## Annex 4-1: Towards monitoring the environmental dimension of the SDGs

### Introduction

The Sustainable Development Goals, the Multilateral Environment Agreement indicators and other indicators related to the environmental drivers, state, pressures, impacts and responses are useful for conducting environmental assessments, including on particular aspects of the environment, and multiple levels (global, regional and national). Additionally, socio-economic indicators can be combined with environmental indicators to better contextualized the environment and to understand the linkages between the environment, people and the economy.

The Sustainable Development Goals (SDGs) are a framework which elaborates the global development agenda toward achieving a better and more sustainable future for all. The Sustainable Development Goals are a call for action by all countries – poor, rich and middle-income – to promote prosperity while protecting the planet. They recognize that ending poverty must go hand-in-hand with strategies that build economic growth and address a range of social needs including education, health, social protection, and job opportunities, while tackling climate change and increasing environmental protection. A monitoring framework of 244 indicators has been agreed for monitoring the SDGs; however, this indicator framework does not represent a complete list of all information that is needed to understand the planet.

The current GEO publication is accompanied by a statistical annex [https://environmentlive.unep.org/media/global\\_assessment/review\\_documents/annex4\\_1.pdf](https://environmentlive.unep.org/media/global_assessment/review_documents/annex4_1.pdf) which includes tabular information to be used by technical experts to better understand the environment and the nexus between the environment, society and the economy. Additionally, this annex extracts certain indicators from the Statistical Annex in order to highlight the current state of progress towards achieving the environment-related SDGs. Note that the Statistical Annex does not include any analysis or figures. An analysis of the information in the Statistical Annex will be forthcoming in a GEO derivate product entitled: Measuring Progress, which is a follow-up to a publication that was produced for GEO-5.

This annex has taken the data in the Statistical Annex which directly links to particular environmental SDGs and extrapolated information in order to provide a summary of the current state of the environmental dimension of the SDGs.

### Statistical Methods

The phrase, the environmental dimension of the SDGs, does not have a precise definition and there are many different views on what the environmental dimension of development should include (should it include only indicators related to the state of the environment, what about indicators related to access to natural resources such as water or perhaps it should include all indicators, since every aspect of life is related to the environment). For the purpose of this analysis, the list of environment-related indicators from the perspective of the UN Environment Programme will be used. A list of SDG indicators which are considered to be part of the environmental dimension of the SDGs was established by the UN Environment Programme Secretariat and was

presented to the UN Environment Assembly Committee of Permanent Representatives at the sub-committee meeting on 20 September 2018 (see: <https://www.unenvironment.org/events/subcommittee-meetings/committee-permanent-representatives-subcommittee-meeting-14>) - it is also included at the end of this document.

The data in the Statistical Annex and in this paper are based on data which are included in the UN Environment Live Global database (<https://uneplive.unep.org>). The data in the database come from a variety of international databases and other sources, UN Environment maintains strict criteria for the information in the UN Environment Live Global database which include:

1. data must be published by a UN agency or other reputable global entity;
2. data must have transparent methodologies and metadata which is publicly available;
3. data must be compiled at the global level (data which is only available for a single country or region is not included);
4. only data with a timeseries which includes more than 2 timepoints is included; and
5. the most recent point in the timeseries must be no more than 10 years old.

The UN Environment Live Global database also uses a statistical methodology for aggregating national data to produce global, regional, sub-regional and special country groupings; information on aggregation procedures can be found at: [https://uneplive.unep.org/media/docs/graphs/aggregation\\_methods.pdf](https://uneplive.unep.org/media/docs/graphs/aggregation_methods.pdf).

This annex uses simple extrapolation procedures to estimate if the SDG targets would be met based on the current state of the SDG indicators (i.e. no efforts were made to change the current data trend). Thus progress in the next 15 years was estimated to be identical to the progress in the last 15 years at a global level. UN Environment extrapolated the aggregated data using the exponential regression model based on available data points from year to year. The cut-off used for data extrapolation and analysis is the year 2030. We determined if the target will be met or not by comparing the 2030 data to the indicator target. For example, if there is an increase in a target by 5% by 2030, it is considered as a positive progress, a change in condition based on this indicator is shown as a positive direction between 2000 and 2030. The same is applied for any decrease higher than -5 per cent. Any per cent change between +5 per cent and -5 per cent has been considered as representing very little negative or positive change in this indicator between 2000 and 2030.

An indicator is considered to have no data if there is not enough data for global aggregation. To determine this we have followed the global aggregation model explained on Environment Live. Where sufficient data are available, aggregations are performed for all indicators which share a common unit and are believed to be internationally comparable. Indicators which are expressed in national currency or another national unit are not aggregated.

## Progress toward the SDGs

Of the 93 environment-related SDG indicators, there are 20 for which good progress has been made over the last 15 years and if this progress continues then it is likely that these SDGs will be met. However, many of these indicators include particular reporting or funding efforts. For example, there has been an increase in terrestrial, mountain and marine protected areas; the effort to combat invasive species has increased; there has been significant progress toward grid-connected renewable energy; sustainability reporting and mainstreaming in policy has increased; and development assistance for climate change and the environment has increased. For 8 of the environment-related SDG indicators the progress has been

relatively flat and for 7 of the SDG indicators, additional efforts will be needed. In particular, many of the indicators related to the state of the environment show a negative trend (these include indicators related to forests, sustainable fisheries, endangered species, domestic material consumption and material footprint). Unfortunately, this is a very incomplete picture because there is too little data to formally assess the status of 58 of the 93 environment-related SDG indicators – however, scientific research and the current GEO has shown that many of these areas have shown a particular negative trend. A snapshot of the progress toward these indicators is shown in the graphic below and an overall table of progress is also shown.

Figure A.4: Relative progress on SDG indicators

**Table A.3: Description of environment relevant SDG targets and indicators in the SDG Global Indicator Framework**

| Goal                                                                                                                        | 70 Targets                                                                                                                                                                                                                                                                                                                                                                                                                                                | 93 Indicators                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

|                                                            | <p><b>Convention on the Conservation of Migratory Species of Wild Animals</b></p> <p>The CMS, or the Bonn Convention aims to conserve terrestrial, marine and avian migratory species throughout their range. Parties to the CMS work together to conserve migratory species and their habitats by providing strict protection for the most endangered migratory species, by concluding regional multilateral agreements for the conservation and management of specific species or categories of species, and by undertaking co-operative research and conservation activities.</p> <p><a href="http://www.cms.int">www.cms.int</a></p>                                                                                                                         |
|                                                            | <p><b>The International Treaty on Plant Genetic Resources for Food and Agriculture</b></p> <p>The objectives of the International Treaty are the conservation and sustainable use of plant genetic resources for food and agriculture and the fair and equitable sharing of the benefits arising out of their use, in harmony with the Convention on Biological Diversity, for sustainable agriculture and food security. The International Treaty covers all plant genetic resources for food and agriculture, while its Multilateral System of Access and Benefit-sharing covers a specific list of 64 crops and forages. The Treaty also includes provisions on Farmers' Rights.</p>                                                                          |
|                                                          | <p><b>Convention on Wetlands (also known as the Ramsar Convention)</b></p> <p>The Ramsar Convention is the only international treaty focused on wetlands. It provides a platform of 170 Contracting Parties working together for wetland conservation and wise use, and to develop the best available data, advice and policy recommendations to realize the benefits of fully functional wetlands to nature and society. The Convention recognized wetlands as ecosystems which are extremely important for biodiversity conservation. Parties to the Convention have already committed to maintaining the ecological character of over 2,300 Wetlands of International Importance covering nearly 250 million hectares, 13-18 per cent of global wetlands.</p> |
|                                                          | <p><b>World Heritage Convention (WHC)</b></p> <p>The primary mission of the WHC is to identify and conserve the world's cultural and natural heritage, by drawing up a list of sites whose outstanding values should be preserved for all humanity and to ensure their protection through a closer co-operation among nations.</p>                                                                                                                                                                                                                                                                                                                                                                                                                               |
|  <p><b>International Plant Protection Convention</b></p> | <p><b>International Plant Protection Convention (IPPC)</b></p> <p>The IPPC aims to protect world plant resources, including cultivated and wild plants by preventing the introduction and spread of plant pests and promoting the appropriate measures for their control. The convention provides the mechanisms to develop the International Standards for Phytosanitary Measures (ISPMs), and to help countries to implement the ISPMs and the other obligations under the IPPC, by facilitating the national capacity development, national reporting and dispute settlement. The Secretariat of the IPPC is hosted by the Food and Agriculture Organization of the United Nations (FAO).</p>                                                                 |

## Annex 9-1: Water Contaminants and Occurrences

|                                    |                                                                                                                                                                                                           |                                                                                                                                                                          |                                                                                                                                                                                                                           |                                                                                                                                                                                                      |
|------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Pathogens                          | Human and livestock excrement (bacterial)                                                                                                                                                                 | Inadequate treatment of sewer effluents; sewer and storm water overflows into rivers, lakes and wetlands                                                                 | 90 per cent of child deaths are caused by diarrheal diseases (WHO and UNICEF 2012).                                                                                                                                       | 1/3 of all rivers in Africa, Asia-Pacific and Latin America regions (UNEP 2016a)                                                                                                                     |
| Parasites (non-bacterial)          | Human and livestock excrement (non-bacterial)                                                                                                                                                             | Human and livestock excrement; septic leakage into surface and groundwater                                                                                               | Approximately half the deaths of children under the age of five years.                                                                                                                                                    | Cities and rural communities in Africa, Asia-Pacific, Latin America, India, Pakistan, China, Nigeria, and Democratic Republic of Congo                                                               |
| Viruses (non-bacterial)            |                                                                                                                                                                                                           | Treated drinking water (Bergeron <i>et al.</i> 2015); natural occurrence in range of concentrations (Kümmerer 2009)                                                      |                                                                                                                                                                                                                           |                                                                                                                                                                                                      |
| Antibiotic/antimicrobial compounds | Human excretion; intensive agriculture and aquaculture practices                                                                                                                                          | Sewer effluents; agricultural and urban runoff                                                                                                                           | Human illness and death due to antimicrobial- and antibiotic-resistant infections                                                                                                                                         | Projected to become a major cause of death worldwide by 2050 (O'Neill Commission 2014)                                                                                                               |
| Nutrients                          | Agricultural inorganic fertilizer (UNEP 2016a); human and livestock excrement                                                                                                                             | Inadequately/untreated sewage discharges; urban and agricultural runoff; aquaculture                                                                                     | Eutrophication and algal blooms (OECD 1982; Research Center for Sustainability and Environment-Shiga University and International Lake Environment Committee Foundation 2014)                                             | All five UNEP regions; rural areas in China, India, Thailand and Philippines also affected by excessive chemical fertilizer application (Novotny <i>et al.</i> 2010)                                 |
|                                    |                                                                                                                                                                                                           | River contributions of total nutrients to coastal areas increased by approximately 80 per cent during 1970-2000                                                          | Effects of harmful algal blooms (HABs) can impact ecosystem functions<br><br>Aquaculture; livestock and human health via bioaccumulation of toxicity. (O'Neil <i>et al.</i> 2012)                                         | Thirty-seven Latin American transboundary rivers are highly polluted with wastewaters and agricultural runoff nutrients at the basin level                                                           |
| Sediment                           | Deforestation; poor agricultural practices; livestock overgrazing; intensive fuelwood harvesting; sand mining; unplanned settlements causing exposed soil surfaces and erosion                            | Storm-generated runoff can carry sediments, nutrients, heavy metals, pesticides and other pollutants into rivers, lakes and wetlands, particularly in agricultural areas | Sediment-associated pollutants interfere with human water use<br><br>Can have health impacts, degrade aquatic organism metabolism and habitats                                                                            | In Asia-Pacific, some rivers carry high loads of sediment-associated heavy metals                                                                                                                    |
|                                    | Changes in sediment flow paths (dykes, channels, urban drainage, dams) can lead to erosion and high sediment loads                                                                                        |                                                                                                                                                                          | Sediment loading to oceans and coastal ecosystems (river deltas, wetlands, beaches, etc.)                                                                                                                                 | 50 per cent of upslope-eroded soil is deposited in White Volta sub-basin in West Africa<br><br>Human-induced erosion has affected approximately 2.2 million km <sup>2</sup> of land in Latin America |
| Biodegradable Organic Pollutants   | Process characterized by a high Biological Oxygen Demand (BOD) from microbial decomposition of human and livestock wastes, and eutrophication-associated algal blooms, particularly in lakes and wetlands | Industrial and domestic wastewater discharges                                                                                                                            | Bacterial-mediated decomposition of algae/aquatic plants can cause hypoxia/oxygen depletion in waterbodies, resulting in fish kills and facilitating release of heavy metals from bottom sediments back into water column | Increasing in African, Asia-Pacific and Latin America (UNEP 2016a)<br><br>in contrast, decreasing in developed countries with enhanced wastewater treatment                                          |
|                                    | Industrial and agricultural applications and operations                                                                                                                                                   |                                                                                                                                                                          |                                                                                                                                                                                                                           | Rapidly-urbanizing and industrializing countries (e.g., China India; Ethiopia; Mexico) and rivers downstream of major Central Asian cities                                                           |

| Water Contaminant                                                                                                                        | Contaminant Sources                                                                                                                  | Pathways into Waterbody                                                                                           | Impacts of Contaminated Water and inadequate Sanitation/Hygiene                                                                                                                                                                                                                                                                                                    | Examples of Occurrence                                                                                                                                                                                                                                                                                                                                                                                                                                                |

|                                          | Lake acidification from atmospheric deposition of fossil fuel emissions                                                      | Acid rain                                                                               | Impacts freshwater ecosystems, including fish and other aquatic organisms                                                                                                                                                                                       | Lake acidification remains problematic in areas lacking soils or bedrock capable of buffering acid rain<br><br>Situation is improving where SO <sub>x</sub> and NO <sub>x</sub> emissions have decreased (e.g., affected lakes in New York Adirondack region recovering at different rates) (Driscoll <i>et al.</i> 2016) |

## Annex 13-1 Biodiversity Conservation and International Environmental Agreements (IEAs)

The University of Oregon has built the most comprehensive database on IEAs to-date. We searched the [iea.uoregon.edu](http://iea.uoregon.edu) database for IEAs related to biodiversity conservation. The search terms "biodiversity" AND "conservation" were used to search for multilateral and bilateral agreements, which returned 45 IEAs in total. Amendments to agreements already deemed relevant were also excluded here to prevent double counting. After the screening process, 33 IEAs were identified that concerned biodiversity conservation. They were signed within three decades (between 1985 and 2015). Four were bilateral

(signed by only 2 countries) and the rest were multilateral (signed by 3 or more countries). Of the multilateral agreements, the number of signatories ranged from 3 to 196 (median = 7). Twenty-eight IEAs focussed on specific geographic regions while six had a global scope. Of those agreements on terrestrial regions, seven focused on conservation of ecosystems or species within North America, five in Europe, six in Asia, and three in Africa. Seven IEAs also focussed on biodiversity conservation in a non-terrestrial context (Indian, Atlantic, and Pacific Ocean, and the Baltic sea).

**Table A.4: List of International Environmental Agreements signed between 2010 and 2015**

| IEA                                                                                                                                                                    | Year signed | Themes |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|--------|
| Agreement on the Protection and Sustainable Development of the Prespa Park Area                                                                                        | 2010        | 4      |
| Nagoya Protocol on Access to Genetic Resources and the Fair and Equitable Sharing of Benefits Arising from their Utilization to the Convention on Biological Diversity | 2010        | 3      |
| Agreement between the Governments of the Member States of the Association of Southeast Asian Nations and the Republic of Korea on Forest Cooperation                   | 2011        | 2      |
| Protocol on Sustainable Forest Management to the Framework Convention on the Protection and Sustainable Development of the Carpathians                                 | 2011        | 2      |
| Protocol on Sustainable Tourism to the Framework Convention on the Protection and Sustainable Development of the Carpathians                                           | 2011        | 2      |
| Agreement on the establishment of the Global Green Growth Institute                                                                                                    | 2012        | 2      |
| Convention on the Conservation and Management of High Seas Fisheries Resources in the North Pacific Ocean                                                              | 2012        | 2      |
| Protocol Amending the Agreement Between The United States And Canada On Great Lakes Water Quality                                                                      | 2012        | 1      |
| Benguela Current Convention                                                                                                                                            | 2013        | 4      |
| Protocol on Sustainable Transport to the Framework Convention on the Protection and Sustainable Development of the Carpathians                                         | 2014        | 2      |
| Paris Agreement under the United Nations Framework Convention on Climate Change                                                                                        | 2015        | 3      |

The IEAs have been categorised into four themes: pollution prevention (1), sustainable use of biodiversity (2), environmental process (3) and protection of ecosystem/species/genes (4) based on the predominant context they fall under.

|  <p><b>Convention on Biological Diversity</b></p> | <p>The CBD has been the key convention in the last two decades for biodiversity conservation, sustainable use of biodiversity and equitable access and benefit sharing of genetic resources (IUCN 2018a; 2018b).</p>                                                                                                                                                                                                                                                                                                                                 |
|                                                   | <p>The need for integrating biodiversity science with policy design, analogous to that which exists for climate change, prompted the establishment of the Intergovernmental Science-Policy Platform on Biodiversity and Ecosystem Services (IPBES) in 2012 (Diaz et al. 2015; Allison and Brown 2017).</p>                                                                                                                                                                                                                                           |
|                                                  | <p>The importance of biodiversity is also recognized in the Sustainable Development Goals (SDGs) 14 (life below water) and 15 (life on land) adopted by world leaders on 25 September 2015 at the UN General Assembly. The clustering of the goals is discussed in chapter 20 (see Figure 20.1)</p>                                                                                                                                                                                                                                                  |
|                                                 | <p>An important response to the need for the protection of biodiversity has been the establishment and management of protected areas, reflected in Aichi Biodiversity Target 11 of the Strategic Plan for Biodiversity 2011-2020. The IUCN defines a protected area as “a clearly defined geographical space, recognised, dedicated and managed, through legal or other effective means, to achieve the long term conservation of nature with associated ecosystem services and cultural values.” (IUCN 2018c). Figure: UNEP-WCMC and IUCN 2016.</p> |
|  <p><b>NATURAL CAPITAL COALITION</b></p>        | <p>The Natural Capital Coalition, which evolved out of the TEEB (The Economics of Ecosystems &amp; Biodiversity) For Business Coalition in 2014 is an international collaboration that aims to mainstream natural capital approaches in the public and private sectors.</p>                                                                                                                                                                                                                                                                          |

## Annex 23-1: Bottom-up Initiative Platforms and Results

| Initiative                                                                                                       | Location                         | Platform Secretariat                             | Platform Participants                                                                         | Description and Projects                                                                                                                                                                                                                                                                                                                                                                                                         | Theory of Change                                                                             | Initiatives | SDGs       | Potential Pathway       | Link                                                                                                                          |

| <b>Singapore [MM81]</b> | Renewable energy microgrids                                         | Renewable energy microgrids implemented in climate and disaster vulnerable areas to strengthen the energy security, resilience and the ability for remote or secluded communities to bounce back from climate events.                                                                                                                                                                                                                                                                                     |
| <b>Singapore</b>        | Celebrating Singapore Shores                                        | Platform to bring together marine groups to celebrate the International Year of the Reefs. This occurs every 10 years.                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Singapore</b>        | Plastic waste footprint calculator                                  | Similar to carbon footprint calculation for individuals, an app/website that approximates the plastic waste footprint of individuals based on their daily lifestyle. The app can then summarize or extrapolate how much the person generates in a week/month/year and provide suggestions on how they can personally tweak their lifestyle to reduce plastic waste.                                                                                                                                       |
| <b>Singapore</b>        | Blockchain open source reporting                                    | Using blockchain as a tool to aid in CSOs reporting. Using technology to ease reporting and measuring data and impact so as it could help CSOs to report and raise awareness.                                                                                                                                                                                                                                                                                                                             |
| <b>Singapore</b>        | Solar Light Cooperative                                             | Decentralized community and cooperative based power grid. Prioritizes poor and underserved communities. Communities manage their own systems and operates like a cooperative.                                                                                                                                                                                                                                                                                                                             |
| <b>Singapore</b>        | Implementation of biomimetics for lifestyle change                  | To keep the linkage between industry and biodiversity conservation. A project to promote biomimicry - technology inspired by nature. Biomimetics as cultural services inspired by ecosystem services. For example, we have swimsuits that are inspired by the skin of the shark, city planning model inspired by the ecosystem itself.                                                                                                                                                                    |
| <b>Singapore</b>        | Marina barrage                                                      | Using barrage as a case study to alleviate flooding issues auto flood gates                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Singapore</b>        | Using Drone to environmental assessment before development          | Collect of Real time environmental informations such as air quality and forest structure                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Singapore</b>        | Repair Kopitiam                                                     | Conducting monthly repair workshops to teach residents in different areas to repair appliances and reduce e-waste. Also involves uploading a series of videos so that anyone can conduct their own workshops. A strength is that everyone can gain repair skills and this also brings back a culture of repairing items.                                                                                                                                                                                  |
| <b>Singapore</b>        | Drainage water level sensors                                        | Sensors to monitor water level of drains and canals to provide real-time site conditions update during heavy storms, to improve response times to floods. This would be really useful for urban cities with dense canal system.                                                                                                                                                                                                                                                                           |
| <b>Singapore</b>        | Melbourne open data platform for environmental management           | Collate information on all the trees in the city of Melbourne                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Singapore</b>        | Satellite imagery to detect the palms health                        | Ability to detect the affected trees without a need to destructive methods.                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Singapore</b>        | Urban Farming by using traditional vegetables                       | Urban Farming in Tokyo Metropolitan area of traditional and indigenous vegetables. Agricultural cooperatives that keep the traditional seeds to promote regional culture and identity. (for example, white radish)                                                                                                                                                                                                                                                                                        |
| <b>Singapore</b>        | Citizen pollution monitoring                                        | Giving citizens the tools to report on local pollution (especially vehicles). One strength is that it leverages pre-existing technology and another strength is that it makes pollution visible.                                                                                                                                                                                                                                                                                                          |
| <b>Singapore</b>        | China Black and Smelly Waters app                                   | Citizens can report instances of foul or smelly water in urban areas through a smartphone app that connects to WeChat. Local government officials have to respond within 7 days to the complaint.                                                                                                                                                                                                                                                                                                         |
| <b>Singapore</b>        | Repair Kopitiam                                                     | "Kopitiam" is a neighborhood coffee shop. This project is run by SL2 (Sustainable Living Lab). Underneath public housing the organization sets up an area where residents can bring down broken items to get fixed. The volunteers teach the residents how to fix electronics, clothing, household and consumer items etc. Typically items of emotional value. Afterwards, pictures are taken. This is set up somewhere around the city every Sunday.                                                     |
| <b>Singapore</b>        | Citizen science reporting                                           | Shared data collected by individuals helping the different cause.                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Singapore</b>        | Carbon dioxide capture for decarbonisation of atmosphere            | Direct air capture of CO2 from ambient air through engineered chemical reactions. The plant sits on top of a waste heat recovery facility that powers the process. Fans push air through a filter system that collects CO2. When the filter is saturated, CO2 is separated at temperatures above 100 degrees Celsius. The gas is then sent through an underground pipeline to a greenhouse.                                                                                                               |
| <b>Singapore</b>        | Seed water                                                          | You can drink water without plastic bottle water                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Singapore</b>        | Seaweed farming for livestock feed                                  | Seaweed as a feed substitute for livestock and dairy cattle. Seaweed has been shown to reduce the amount of methane produce by ruminating animals.                                                                                                                                                                                                                                                                                                                                                        |
| <b>Singapore</b>        | Transport Network Vehicle Systems                                   | Big data-based transport system. Users hail rides in the most convenient way using smart phone apps. Offers lower ownership costs per passenger-km and reduces environmental impacts of transport. It is a potential solution to reduce private car use. People get to share rides, while still having the comfort and convenience of private transport.                                                                                                                                                  |

| Singapore | Smart Farm                                                                    | Smart farm uses a variety of technologies to monitor the state of vegetables. It helps farmers to know how much the vegetables and fruits need the sun and waters. It helps to make sure the food security.                                                                                                                                                                                                                                                                                                 |
| Singapore | Karthavyam (Dutiful citizens for SDG)                                         | A hands on student diploma on public problem solving through the Sustainable Development Goals. The diploma is a 6 month programme with 4 pathways where children are taught via films, podcasts, and other media that can be easily shared. Classes involve experiential learning, designing localized initiatives, writing story books, watching films, and engaging with the community. A strength is that it uses visual mediums (filmmaking) to create a decentralized platform for knowledge sharing. |

| Singapore | Repair Kopitiam                                                               | Bring residents together to learn how to repair broken appliances in order to reduce waste. It also aims to reduce consumption, and also equip residents with employable skills. At the same time, it also preserves legacies of twilight industries (such as cobblers, etc.)                                                                                                                                                                                                                               |
| Singapore | Great British Bee Count                                                       | Individuals are encouraged to engage with bees (and biodiversity) by taking photos of bees and sharing it on a centralized platform. Individuals can also buy bee saving materials to plant flowers in neighbourhoods in exchange for photos of bees. A strength of the initiative is that it allows for data collection on bees. Additionally, it leverages pre-existing technology.                                                                                                                       |
| Singapore | Global Circular Economy Database                                              | A database that captures circular economy initiatives and sharing the information on a central platform. A strength is that it can mobilize many different groups to contribute to the database without much effort. This database can then act as a learning platform for others.                                                                                                                                                                                                                          |
| Singapore | Edible cutlery                                                                | Cutlery made from wheat, rice, and sorghum. There are over 160 million tons of plastic cutlery used in India every year. An initiative sponsored by the Govt of India.                                                                                                                                                                                                                                                                                                                                      |
| Singapore | horticulture along the banks of perennial rivers in India                     | The idea would be to replace plants by trees along the banks of perennial rivers in order to prevent soil erosion and to promote economic growth for farmers.                                                                                                                                                                                                                                                                                                                                               |
| Singapore | Trash to Treasure (Free flea market)                                          | A free flea market where personal items and belongings that are unwanted can be redistributed to those who need them or could better utilize them. A strength is that it's free for everyone, can be organised anywhere, and doesn't require any technology.                                                                                                                                                                                                                                                |
| Singapore | Green Roofs                                                                   | Planned and built green roofs and not just those green roofs that are imposed upon existing buildings. These green roofs can reduce energy use from air conditioning. Well built green roofs also collect rainwater and reduce the flow fast-flowing water, and also reduces the risk of flooding in flood-prone areas. Provides habitat for biodiversity.                                                                                                                                                  |
| Singapore | carpooling                                                                    | encourage students and faculty members of a given university to use carpooling as much as they can                                                                                                                                                                                                                                                                                                                                                                                                          |
| Singapore | Setting up of Wormery                                                         | The setting up of wormeries allows for the decentralization of food waste collection. Food waste is collected locally and composted locally using earthworms. The castings (worm poop) are used as fertilizers and they are sent to the community gardens.                                                                                                                                                                                                                                                  |

| Singapore | Refugee crisis management                                                     | Using technology to help refugees like a message alert that can reach out to them                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Singapore | Fresh Direct Container Farms                                                  | A Nigerian entrepreneur turned shipping containers into indoor governments, and employ mainly needy women                                                                                                                                                                                                                                                                                                                                                                                                   |
| Singapore | Smartphone app to monitor energy consumption                                  | Powershop is a company that provides an app platform that enable consumers to track the energy consumption of their home. The tracking is live and accounts for energy inputs from solar PV. The app also provides monetary incentives to reduce consumption by displaying \$ values supported from solar energy input which supports conscious consumption and transition to renewable energy.                                                                                                             |
| Singapore | Solar-powered Water Purification                                              | Used by local communities for water filtration and sanitation. Filtration system within a bottle which allows communities to use the water.                                                                                                                                                                                                                                                                                                                                                                 |
| Singapore | Green Building Standards                                                      | Setting standards for new buildings construction and renovations                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Singapore | App for plant identification                                                  | The app helps to identify trees, plants, and flowers. People who see unknown plants, they can take a photo using the app. It plays a significant role in educating people.                                                                                                                                                                                                                                                                                                                                  |
| Singapore | AI driverless electric cars                                                   | To integrate AI INTO our transport system                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Singapore | Palm oil-targeting activist organizations like People's Movement to Stop Haze | The seed initiative tries to promote the use of sustainable palm oil in the Singapore market by engaging both F&B sector (supply side) and consumers (demand side).                                                                                                                                                                                                                                                                                                                                         |
| Singapore | Precious Plastic                                                              | A startup that provides open-source guides and designs for communities to create plastic recycling machines and tools. The startup provides support and guidance for anyone interested in creating such machines. A strength is that all the information is open sourced and it allows decentralized recycling initiatives to emerge.                                                                                                                                                                       |
| Singapore | Youth Ki Awaaz                                                                | A decentralized online platform for people to write stories on social issues. It allows anyone to create a campaign and facilitate change. Additionally, stories are powerful in tackling global challenges and this platform allows anyone to participate.                                                                                                                                                                                                                                                 |
| Singapore | Wearable devices                                                              | Wearable devices for people's health                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| Workshop  | Seed Name                                               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| Singapore | Gaia Grid                                               | An off grid farming community that uses crowdfunding and social media to create a self sustaining community. It co-ops tribal villages, weeds out social problems, and encourages organic farming.                                                                                                                                                                                                                                                                                                                                                                                                         |
| Singapore | Gravity Light                                           | Using gravity to create electricity                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Singapore | Safe spaces for deep conversations on climate change    | A NGO that trains facilitators to help facilitate home-based, friend networked conversations on climate change. This activates individuals to lead community actions.                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Singapore | Street Feeders of KL                                    | A regular gathering of volunteers to distribute perishable and non-perishable food to the homeless. This also helps increase the understanding on the background of the homeless. The homeless can also be linked to job opportunities. A strength is that this facilitates face-to-face conversations that help connect communities with the homeless. It also offers hope to the underprivileged.                                                                                                                                                                                                        |
| Singapore | UN REDD+ Carbon Credit System in a Quirino Protected    | To restore fragmented landscapes and promote planting of fruit trees (for food security as well) and provide subsidy to Farmers for being advocates of the protected area                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Singapore | Sharks Fin Database                                     | A centralized database that allows citizens to share the location and names of restaurants that serve sharks fin. This creates awareness of these restaurants and allows citizens to boycott or engage with the restaurants that serve sharks fin. A strength is that this is citizen sourced data that leverages existing technology and is low cost.                                                                                                                                                                                                                                                     |
| Singapore | No Straw Tuesdays                                       | Plastic-lite started 1.5 years ago as a way for people to reduce and be mindful of their plastic consumption. Volunteer-run, self-funded group. Rolling out initiatives among communities to promote lifestyle changes. Taps into the power of social media to galvanise participants. 'No Straw Tuesdays', rolled out in schools one day a week.                                                                                                                                                                                                                                                          |
| Singapore | GrabHitch                                               | A technology platform that connects non-taxi drivers and riders to facilitate carpooling in order to reduce the number of cars and fuel demands. This leverages existing technology and apps to reduce the number of cars on the road.                                                                                                                                                                                                                                                                                                                                                                     |
| Singapore | Amsterdam Rain Proof programme                          | Harnessing urban water runoff for alternative products eg. beer and closing the water loop.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Singapore | Bitcoin Mining Heater for Homeless                      | Bitcoin mining releases lot of heat energy.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Singapore | Dog Poo Bag Station                                     | Provide self sustainable and convenient way to encourage do owners to clean up after their pets, for pet owner to share their unused dog poo plastic bag with fellow pet owners, to clean up dog poo.                                                                                                                                                                                                                                                                                                                                                                                                      |
| Singapore | Making of pet plastic bottles into t-shirts             | Tzu Chi charity employs the use of disposed pet plastic bottles and upscale them into t-shirts and blankets, which are then donated to victims of natural disasters                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Singapore | Lendur (app)                                            | P2P library of things (e.g. household objects) that users can borrow, instead of buying for one-time use                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Singapore | Innisfree Empty Bottle Recycling Campaign               | Customers can bring used containers back to stall (up to 50 points redeemed), get discount on future purchases. Campaign uses statistics on how many bottles have been recycled and repurposed. Appeals to consumers, "feel-good" aspect.                                                                                                                                                                                                                                                                                                                                                                  |
| Singapore | 500 Women Scientists                                    | Improve openness, equality in science in Latin America. Goal to create scientific culture, promote scientific literacy, embrace technology and sciences. Grassroots movement - get people to recognise the presence of female scientists in particular. Host social events on a monthly basis, invite individuals to chat, speed-dating style. Mentoring, going to schools and talking to girls about S&T, policy in government, does not seem accessible, sense of cultural inferiority (for the Old White Man), means of decolonizing academia and science.                                              |
| Singapore | Swapaholic                                              | Online clothes swapping platform. Participants bring in pre-loved, quality clothing in exchange for points that can be spent at clothes swapping events hosted around Singapore on a regular basis.                                                                                                                                                                                                                                                                                                                                                                                                        |
| Singapore | Plastic Footprint Calculator                            | <a href="http://whatismycarbonfootprint.com/plastic-footprint">http://whatismycarbonfootprint.com/plastic-footprint</a> - Calculates an individual's plastic footprint, aiming to use information to educate and reduce usage of plastics.                                                                                                                                                                                                                                                                                                                                                                 |
| Singapore | Plastic Bank (app)                                      | <a href="https://www.plasticbank.org/what-we-do/">https://www.plasticbank.org/what-we-do/</a> - Turns waste into currency by incentivising individuals to collect plastics in exchange for rewards which are distributed and authenticated through the Plastic Bank app which uses Blockchain technology. Transfers values into the hands of those who collect plastic.                                                                                                                                                                                                                                    |
| Singapore | Vegan/Vegetarian UN Environment Meals                   | Provide vegan/vegetarian options during meals at UN/INGO conferences and events to showcase that vegan/vegetarian meals.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Singapore | Local Water Commissions                                 | Community-organizing in the event of a drought/water rationing, to pool resources, help less abled members collect water, draw on connections. Can also be applied to energy sharing and food security.                                                                                                                                                                                                                                                                                                                                                                                                    |
| Singapore | Grab (app)                                              | Ride-hailing app, expanded to GrabShare, GrabHitch, incentivise passengers by using cheaper prices as opposed to riding individually. Reduces fuel consumption, company can mobilize clean energy vehicles (e.g. electric cars).                                                                                                                                                                                                                                                                                                                                                                           |
| Singapore | First climate change course in a Costa Rican University | Addresses lack of existing climate change education and communication in the country                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Singapore | SECM DL                                                 | An alternative learning school for youth established by local youth in a community. A strength of this is that it is a decentralized, replicable, and self-sustaining project that can be transferred to other communities.                                                                                                                                                                                                                                                                                                                                                                                |
| Singapore | Plant Diet/Veganism                                     | include and promote more plant-based menus                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Singapore | Sustainable Aquaculture                                 | Integrates multi-trophic systems, using outputs (e.g. waste) of a species as inputs (e.g. food) for species up the chain. Also sources for local/indigenous species to breed in Singapore, to encourage Singapore's heritage, change tastes and preferences to reduce carbon footprint from food imports.                                                                                                                                                                                                                                                                                                  |
| Singapore | Superwomarket                                           | A supermarket/cafe designed by women scientists filled with products they selected. It will have:<br>- Products showing carbon/water footprint and relevant SDGs<br>- Products with minimum wrapping<br>- A breastfeeding and expressing space, which will also have a sit-in nurse who can check/give guidance for breast cancer<br>- A communication space (cafe) for women to network, conduct events, etc.<br>- A childcare space with a sitter where young children can play while the mothers are shopping or networking<br>It will provide a "safe environment" for women to share their expertise. |

| Workshop  | Seed Name                                                                        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| Singapore | Greening the GEO Conference                                                      | <p>The next GEO meeting will be more green. We must practice what we preach. It could potentially include: vegetarian/vegan meal options, remote conferencing options using conferencing robots (e.g. "Double")</p> <p>(This will be an inclusive option for persons who cannot travel, such as those like myself who cannot travel due to childcare, or persons with mobility issues), paperless, less air conditioning, sustainable hotel practices, smaller carbon footprint (less plastic), sourced by renewable energy</p> <p>The existing 2009 UN Environment guidelines (<a href="http://www.greeningtheblue.org/sites/default/files/GreenMeetingGuide.pdf">http://www.greeningtheblue.org/sites/default/files/GreenMeetingGuide.pdf</a>) could be updated through online consultations with the GEO authors (e.g. "what do you want to see in the next GEO conference?"), and then e-published together with GEO-6 as a spin-off product.</p> |
| Guangzhou | Reduce the consumption of wildlife                                               | <ul style="list-style-type: none"> <li>- Reduce consumption of wildlife (e.g. do not eat wildlife)</li> <li>- Reduce the purchase of wildlife products</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| Nairobi  | Biogas (waste)                                                  |                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Nairobi  | Earth Observation                                               | "Sanivation" and "locate it." Task force on high resolution spatial data to track deforestation in school, health, transport, and energy. The seed requires technology, evidence (??), and communication. Very simple app, upload to Airbus platform. The seed is just starting up in Norok County, Nairobi. The seed is innovative as it is a low-cost application and a global platform. Addresses SDGs 3, 4, 10 |
| Nairobi  | Education - connectivity of schools                             | Use technology to produce quality education. Use kindles instead of wastes and reduce paper use. Addresses SDG 4.                                                                                                                                                                                                                                                                                                  |
| Nairobi  | Affordable air quality monitoring                               | Low cost sensor devices                                                                                                                                                                                                                                                                                                                                                                                            |
| Nairobi  | Crowdsourcing behavior with smart apps                          |                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Nairobi  | Products from plastics                                          | Produce petroleum products from plastics, reuse plastics. Innovation from producing threads of 3D printing. This seed has a "microeconomy approach."                                                                                                                                                                                                                                                               |
| Nairobi  | Awareness building                                              |                                                                                                                                                                                                                                                                                                                                                                                                                    |

| Workshop | Seed Name                                                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| Nairobi  | Ecoflame - toilet that separates solid/liquid waste               | Solid waste management system that recycles waste to produce biogas. This technology produces energy from compost. Portal toilets fit within houses. Waste is baked in a 90 degree parabolic mirror and turned into charcoal. Ecoflame has been in use for a while and has over 10,000 users in Naivasha (??). The product does not smell                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Nairobi  | Residential rooftop solar energy                                  | Catalyst for creating social awareness for energy issues. Addresses SDGs 13, 9, 7, 11. This seed is gaining momentum globally. Example from Pham Binh (Vietnam), Durga Prasad Dawadi (Nepal), and Peter Mburu (Kenya)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Nairobi  | Smart energy                                                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Nairobi  | Rooftop rainwater harvesting                                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Nairobi  | Water/agriculture management in Iran (small grant program by GEF) | Water management Iran to address local community and health. The seed has many small projects to engage communities and farms to prevent dust and sand storms. Addresses SDGs 1, 6, 8, 17. The seed is already established and engaging with government and local communities. This seed is currently operating around the border of Iran and could scale up to neighbouring countries to address desertification. The seeds main weaknesses are its difficulty to link national government and local communities' civil society. Several actors are involved including the media, government, local communities, private sector, banks/investment.                                                                                                                                                                              |
| Nairobi  | Protected areas in Madagascar                                     | Protected areas in the east of Madagascar for the Credit Carbon, reducing deforestation, and promoting smart climate agriculture. The seed addresses SDGs 2, 3, 6, 7, 8, 13, 15. Deforestation is prevented through alternative economic opportunities. The seed's main weaknesses include the need to promote across the rest of the country the idea of climate smart agriculture, and it is unclear if people will accept new ideas/ approaches. Actors involved include the rural population and local government.                                                                                                                                                                                                                                                                                                           |
| Nairobi  | Electric cars/Tesla and trucks                                    | This is an established seed that addresses SDGs 3, 7, 8, 9, 11, 12, 13. It is based in EU, US, China, and some ME countries. The seed replaces diesel/gasoline vehicles. With the Tesla app you can get real-time info on the vehicle through the software integration in cars. Particularly promising is that Beijing sells more EVs than regular vehicles with a 40 per cent subsidy of the cost from the government. Three main weaknesses can be identified: (1) energy infrastructure issues if electricity generation comes from coal or fossil fuels, (2) congestion problems can just get worse, (3) rebound effect, (4) competition with e-bikes. Actors involved include business, consumers, and individuals. Superchargers, hydrogen batteries (and other tech breakthroughs) could make EVs faster and easier.      |
| Nairobi  | Innovative public transport                                       | This includes e-ships for public transport and tourism. The seed addresses SDGs 3, 7, 8, 9, 11, 12, 13. It currently in start-up phase and based in Iraq. The ships are to be cheaper for consumers, energy efficient, faster, can alleviate road accidents, reduce congestion, and improve safety. Weaknesses include congestion, potential conflict with water, could conflict with pollution of air, water, waste. Actors involved include business, govt, and individuals.                                                                                                                                                                                                                                                                                                                                                   |
| Nairobi  | Car and bicycle sharing                                           | This addresses SDGs 3, 7, 8, 11, 12, 13. It is established and in use in at least hundreds of cities (Mobike in 110 cities). The seed uses clean energy, is a low cost solution, and easy to implement/upscale. Major weaknesses include the need for an app/smart phone, too many bikes lead to crowding and accidents. Enabling conditions include infrastructure and critical mass; proper education and respect for cultural issues, many co-benefits for integration with other smart-city initiatives.                                                                                                                                                                                                                                                                                                                     |
| Nairobi  | E-pay initiatives/cashless systems                                | This seed addresses SDGs 5, 9, 8, 12. It is established in some countries and a start-up in others, but examples can be found globally. It is innovative as it adds convenience, reduces the need for cash, and allows for easier exchanges. There is a global megatrend towards this seed and can help with sustainable consumption and production. The seed's main weaknesses are waste and the increased consumption of solid waste.                                                                                                                                                                                                                                                                                                                                                                                          |
| Nairobi  | Reduce packaging                                                  | Optional packaging when purchasing goods, package free shops, plastic bag bans, taxes. This seed addresses SDGs 2, 6, 9, 11, 12, 13. It is at the start-up stage and examples can be found in Dresden, Germany and other places. It is innovative and beneficial as it includes: (1) biopackaging from agricultural waste which closes system loops, (2) reduces food waste, (3) incentive alternatives, (4) visible and a good communication tool. It is a very scalable solution. There are three main weaknesses: (1) bulk/wholesale - health/sanitary issues, (2) alternatives to plastics could be worse and potentially increase the amount of bags used, (3) compostable/biopackaging needs inputs that add stress to agriculture. Actors involved include citizens and governments, business, urban shops and retailers. |

## Workshop Seeds-Based Visions

| Workshop       | Pathway                                             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|----------------|-----------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Bangkok</b> | Smart Communities (Decentralized Solutions focused) | <p>This alliance proposed a vision and an approach for developing what they described as “smart communities” – a new and radically different vision for future built environments. The basic premise of the envisaged future presented here, is to challenge the conventional model and principles of urbanism and the traditional processes through which existing cities grow, evolve and function. The idea which builds on the so-called New Urbanism concept seeks to address the disconnection between the current models of urban/ city-planning and interactions at the peri-urban interface that characterize today’s-built environments. For example, the group aimed to address the inefficiencies with urban and suburban sprawl, simplistic and counterproductive patterns of metropolitan growth, perverse incentives around infrastructure investment, rural-urban migration etc.</p> <p>The proposed Smart Communities Alliance brings together several common elements and mutually reinforcing attributes that lead to development of smarter and more sustainable communities. The main ‘seeds’ or game-changers ideas that are part of this alliance include: circular economy, sustainable peri-urban agriculture, microfinancing, intelligent and sustainable transportation systems, and public/ community awareness. This alliance proposes to address all five regional environmental challenges identified. The group felt that the Smart Communities vision was relevant to all 17 Sustainable Development Goals but in particular those related to 1, 3, 6, 7, 11, 12, 13 and 17 with an emphasis on the following synergies: smart changes, behavioural choices, sustained investments in R&amp;D, innovation and clean technology, political and social adaptability (and adaptive governance). Finally, as a point of clarification, the group indicated that the intention of the Smart Communities was not to convert existing large cities, but rather, to shape future build environments and areas that are currently in the early stages of urbanizing.</p> <p>The Smart Communities Alliance received a final score of 17 and succeeded in addressing a number of Sustainable Development Goals and leveraging synergies between urban sustainability objectives and sustainable (or eco-centric) urban infrastructure investments. One of the most important enabling conditions for bottom-up approaches to succeed is sustainability, and the need for gap analysis. Here, the alliance was able partially successful, however a major shortcoming was a lack of discussion on the need for social and political acceptability.</p> |
| <b>Bangkok</b> | Smart Future (Lifestyle Change focused)             | <p>The second alliance in the visioning exercise, proposed a holistic approach to bringing together and catalyzing large-scale behavioural changes through a process of “influencing the influencers”. Here, the alliance stressed the importance of finding a new delivery mechanism to identify who the main private and public sector leaders (or influencers) are to communicate a single value proposition about the Sustainable Development Goals.</p> <p>As a secondary approach, the alliance discussed the need to target consumers, and to leverage the opportunities brought about through big data/ data revolution. The alliance suggested that the Smart Futures vision was relevant to all 17 Sustainable Development Goals and addressed all five regional challenges. The common attributes of this alliance include: disruptive innovation technologies (e.g., smartphone applications, cloud computing, social networking), data-driven decision systems, sustainable/ smart cities, agro-economy solutions, highly inclusive/ people-centric initiatives, integration, meaningful private-public partnerships, and results-based performance to improve decision-making processes.</p> <p>The Smart Futures Alliance received a final score of 9 from the SAP and despite some promising game-changing ideas, and several areas of convergence, the alliance was ultimately unsuccessful as they rolled a higher dice. Reflecting on the process, the group found that the principal barrier was that their ideas were too broad and that their main inputs were spread across too many competing (and sometimes mutually exclusive) objectives.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Bangkok</b> | Planet Tech (Global tech focused)                   | <p>The third and final alliance was the ‘Planet Tech’ group presented a futuristic, hyper technology rich vision of the future with a focus on planet altering technologies and of Earth systems including: geoengineering/ carbon capture storage technologies, mesopelagic exploration, planetary tech, and artificial intelligence. The proposed vision was predominantly geared towards addressing macro/ planetary scale environmental challenges including climate change, biodiversity and complex atmospheric-ocean related issues. The common thread for this alliance was the potential for plenary harm and conversely opportunities for transformational ‘planet-alerting’ solutions. The main Sustainable Development Goals that the Planet Tech Alliance was targeting include 12, 14 and 17.</p> <p>Several institutional obstacles and gaps were identified including mechanisms to circumvent conflict, intergovernmental and global governance issues (e.g., UN Security Council issues).</p> <p>The Planet Tech Alliance received a final score of 8 and struggled with a scenario that was overly complex, far too doomsday oriented and ultimately not inspiring or compelling enough. Their high dice roll meant that their scenario also did not succeed. The group acknowledged that the overall concept was not conducive and/or accessible enough to attract meaningful political engagement and that they needed to refine their technology dominant strategy.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| Workshop  | Pathway         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| Guangzhou | Proposal 1      | <p><b>How are the seeds combined?</b><br/>The habitat is essential for survival. In order to ensure coexistence between humans and animals, new and appropriate links must be developed.</p> <p><b>How does the proposal help realize the pathway – toward what SDGs?</b><br/>To provide better habitat condition for animals, which do good for biodiversity.</p> <p><b>What policy changes are needed to help realize the proposal in this pathway? How can policies help deal with any trade-offs related to other SDGs?</b></p> <ol style="list-style-type: none"> <li>1. Public awareness of animal protection</li> <li>2. Laws and regulations for animal protection</li> </ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Guangzhou | Proposal 2      | <p><b>How are the seeds combined?</b><br/>These seeds have similar features, which could share similar support on policy and addressing mechanism.</p> <p><b>How does the proposal help realize the pathway – toward what SDGs?</b><br/>Nowadays online shopping produces large amount of plastic waste, which is difficult to be either recycled or degraded and also causes significant environmental burden. By limiting use of plastic and solid wood furniture, negative environment impact caused by these could be reduced.</p> <p><b>What policy changes are needed to help realize the proposal in this pathway? How can policies help deal with any trade-offs related to other SDGs?</b></p> <ol style="list-style-type: none"> <li>1. Implementation of Plastic Limit.</li> <li>2. Waste management and categorization.</li> <li>3. Concrete policies and regulations need to be developed under framework of environment protection law.</li> <li>4. Public awareness of environment protection</li> </ol>                                                                                                                                                                                                                                                                                                                                                                                     |
| Guangzhou | Proposal 3      | <p><b>How are the seeds combined?</b></p> <ol style="list-style-type: none"> <li>1. Constructions and facilities are everywhere in the community, advanced energy techs can be applied.</li> <li>2. Model sustainable community is easy to scale up, copy and paste.</li> <li>3. Communication and cooperation between communities, cities and different countries are helpful to combine all the seeds.</li> <li>4. Community could be the “lab” for green tech.</li> </ol> <p><b>How does the proposal help realize the pathway – toward what SDGs?</b><br/>This proposal could help achieve following goals:<br/>Goal 3: Ensure Health and Well-being<br/>Goal 4: Quality Education<br/>Goal 6: Clean Water and Sanitation<br/>Goal 7: Affordable and Clean Energy<br/>Goal 9: Industry, Innovation and Infrastructure<br/>Goal 11: Sustainable Cities and Communities<br/>Goal 12: Responsible Consumption and Production<br/>Goal 13: Climate Action<br/>Goal 17: Partnerships for the Goals</p> <p><b>What policy changes are needed to help realize the proposal in this pathway? How can policies help deal with any trade-offs related to other SDGs?</b></p> <ol style="list-style-type: none"> <li>1. Campaigns to raise public awareness</li> <li>2. Cut land and tax policy</li> <li>3. Public fundings from government</li> </ol> <p>These aspects could help increase energy efficiency.</p> |
| Nairobi   | Behavior change | <p>Use seeds for ISO-like framework to standardize sustainability for national governments (i.e., standards for waste, recycling, packaging, etc.)</p> <p>Policy changes needed/trade-offs related to other SDGs:</p> <ul style="list-style-type: none"> <li>- UN resolution</li> <li>- national level legislation</li> <li>- how to sell to national govts - competitive advantage, better business opportunities for leading companies</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| <b>Nairobi</b>   | Decentralized Solutions                                       | <p>Consists of climate smart agriculture, protection of forests, healthcare and promotion of gender equality</p> <p>Seeds are combined with guidance from national/local committees. SDGs addressed: 1,3,10,11,13,15,17,16</p> <p>Challenges: linkages between national and local community/ potential risk to marine life, and sending messages to high-level policy makers and media to increase public awareness</p> <p>Policy changes needed/trade-offs related to other SDGs:</p> <p>Potential risk to marine life is there is an increase in agricultural fertilizer. Need for strengthening link between local governments and communities. Inviting investment from private sector. Need to work across silos between healthcare, agriculture, forest protection. Need to identify and engage all stakeholders to increase public awareness. Important for high-level policymakers to understand local activities - GEO can help facilitate this.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

Biomimicry technology and ride sharing further promote the community's sustainability                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Singapore</b> | No impact on the environment                                  | They can be implemented in the same institution, namely the university or a private company                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Singapore</b> | Change from Consumers to Community                            | All relate to sharing rather than consuming and building communities                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Singapore</b> | Energy efficient community                                    | Green building standards require a wide set of sustainability building and renovation rules, and require roofs to be used by solar cooperatives.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Singapore</b> | Sustainable Urban food production and consumption             | Both seeds reduce waste from food consumption, and address sustainable production of food.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Singapore</b> | Community resilient gardens                                   | Goals: SDG 10, 2, 12, 13, 3, 8, 6. The proposal aims to create synergies between the different seeds proposed by incorporating different metrics and initiatives of environmental sustainability with the fair employment of employees that are mentally challenged.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Singapore</b> | A Containerized, Modular, Sustainable City                    | Each of our seed in this proposal address a specific urban city challenge, with the function/technology of the seed being transformed into to create a transportable container module which makes up the building blocks of a sustainable city.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Singapore</b> | Urbanites (engaging citizens in community environment action) | <p>Create an international cities platform online where data and environmental action is aggregated. Multiple features are included on this platform, including environmental education, citizen information reporting, enforcement, skills education embedded in circular economy concepts and also logs/pins where activities are for the nearby communities to participate in. SDG 17 is fulfilled through multiple partnerships</p> <ol style="list-style-type: none"> <li>1. Safe space conversations to tie sustainability to very local impacts (SDG 13)</li> <li>2. After activating these citizens, they contribute by engaging with this online platform. They can choose to be active citizen information providers, signing up for skills education etc... (SDG 12, 11, 4)</li> <li>3. The platform is not a passive platform but actively engages experts and practitioners. E.g., citizen reporting of biodiversity can be linked to Researchers; citizen reporting of vehicle or water pollution is linked to regulatory enforcement officers, after finishing skills education they can provide paid services (SDG 3, 4, 8)</li> <li>4. Education arm of the app provides both environmental and skills based education (aka udemy but specialized in environment such as circular economy, repair, waste management, composting skills etc) (SDG 4, 9)</li> <li>5. Aggregation of multiple community initiatives, including waste reduction, plastic pollution, biodiversity, poverty and hunger (SDG 1, 2, 15, 14) learn from different cities and communities as everyone will upload their initiatives to this platform</li> <li>6. App enables easy access to action</li> </ol> |

| Workshop         | Pathway                                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| <b>Singapore</b> | 500 Cientificas (500 Women Scientists) | Getting people to know female scientists (perhaps due to our family-oriented, traditional culture female scientists will be perceived as more approachable, as most people identify with the "advice of a mother or a sister". This will help create a local science culture and improve scientific literacy. By working with other seeds we can increase the reach of female scientists, motivate women to incur in traditionally male-dominated fields, and improve equality and access.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Singapore</b> | Off Grid Rural Development             | <p>Gaia Grid is the foundation of the seed proposal - crowdfunding from social media to purchase degraded non-forested land. Regional farmers are mobilized to do organic farming on the land. Volunteers from the community that need jobs and skills development are invited to help. Farm uses off-grid clean energy. Volunteer programme is set up to develop framing skills that can be used for future integration back into society and explicitly addresses social issues such as alcoholism and drugs that plague the neighbouring community. (SDG 1, 2, 3, 7, 8, 12)</p> <p>By connecting to additional seeds we achieve extra SDGs synergistically:</p> <ul style="list-style-type: none"> <li>- Environmentalist foundation of India: explicitly uses land and water restoration projects and tools (SDG 6, 15)</li> <li>- SECMDL; Karthavyam; Youth Ki Awaaz: Alternative education which provides bottom-up experiential learning and skills development through mediums like story-telling, filmmaking and using local issues and indigenous local knowledge and perspectives (SDG 4, 18)</li> <li>- Safe Spaces for Deep Conversations on Climate Change: Introducing climate change perspectives into community conversations using issues that are very relevant to the community to bring abstract global debates into a local context (SDG 13, 17)</li> <li>- Watly: Bringing access to technology to rural areas in order to give communities access to global networks (SDG 9)</li> </ul> |

| <b>C'SQUARE - Urban Comfort Rating</b>                                                   | C'SQUARE is an online-based application with the objective of empowering citizens by rating places in urban areas concerning their comfort level (thermal comfort, air and noise pollution, security, safety and beauty/cleanliness) and proposing solutions for solving trade-offs to minimize its impact on the environment.                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Youth Informing Communities on Climate Change Adaptation through building homes</b>   | We are putting forward a strategy encouraging youth to lead an environmentally efficient, educational strategy through the expansion of housing. The solution will promote environmental education with the skill to adapt to future issues in First Nations communities in Canada.                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>An innovative model harmonizing ecology, emotions, and economy of the villages</b>    | A model Ecovillage showcasing fulfilment of the village community needs of food, water, waste, and energy while meeting the maximum SDGs                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Local organization for the promotion of environmental data analysis</b>               | This proposal proposes the implementation of local agencies that address this problem in a systemic and proactive way, working in conjunction with government agencies, academic institutions and different groups of civil society.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Global complementary currency pegged to the production of organic living biomass</b>  | The Organic Monetary Fund, set up as a division of the International Monetary Fund, will help to achieve almost all SDGs in record time                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Adding value to all waste at source through blockchain technology and IoT</b>         | Recyclebot is a blockchain-based waste management platform that allows any waste buyer to source specific waste directly from the producer, giving you the ability to buy, sell and reduce waste wherever you are, when you want. Unlike landfills, Recyclebot provides an affordable, fast and safe way to add value to all waste right where it is generated.                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Synergistic Solutions Global Network</b>                                              | Networking existing resources and engaging women and youth to deliver proven solutions to address ten Sustainable Development Goals.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Leo Leo Eco-Transport</b>                                                             | Leo Leo Eco-Transport aims to foster economic empowerment and promote food security while ensuring sustainability in Arusha city. Leo Leo Eco-Transport is proposing a visionary and innovative synergistic solution to sustainable development of food security, reliable access to solar energy utilization, economic empowerment, employment opportunities and climate change that affects the surrounding environment.                                                                                                                                                                                                                                                                                                          |
| <b>Beekeeping as mechanism of biodiversity conservation and livelihoods improvement</b>  | Alohen, partnering with Barefoot College, will establish adoption of beekeeping practice in Tanzania. Following its expansion strategy, Barefoot will further develop the project in Madagascar, Liberia, India and Pacific Islands, through its network of training centers worldwide. The main objective of the project is to create conservation awareness, empowering on the modern beekeeping methods, targeting women from rural areas and supporting them by creating local social enterprises based on bees' byproducts. Such project was initiated by BC in Zanzibar in 2015, creating the B.Barefoot Honey brand to provide trainings and markets for local women beekeepers. Replication was initiated in India in 2016. |
| <b>New clean energy tech will reverse climate change, eliminate world poverty</b>        | Disruptive 0E energy tech works better than fossil/nuke at a better value, based on a new, previously undocumented aspect of physics.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Media houses and institutions for communication awareness on the 17 SDGs</b>          | Media Groups are mainly associated with local political issues and propaganda, rather than ensuring communication awareness on the 17 SDGs.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Binder-less board made from coconut husk and sugarcane bagasse</b>                    | Ecovon are developing sustainably sourced, newly engineered wood made from coconut husk and sugar cane bagasse better for people and planet.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Culturing the future with permaculture</b>                                            | Build a physical Permaculture Resource Hub. A space where people can network with individuals and projects, as well as catalyze community organization and action. Our mission is to build resilience at the personal, household and community levels while creating thriving examples of abundance based on ecological wisdom.                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Climate protection by the elderly</b>                                                 | A brief, the elderly plants a fast growing fruit bearing tree rich in proteins and minerals. Once the tree starts bearing fruits, these fruits are then distributed in the market by either his children or son in laws. His children will be given an incentive of Rs 100 for the work of transporting the commodities to the government market. Once the government procures the fruits it distributes it to the anganwadis, orphanages and old age homes free of cost under ministry of social welfare scheme.                                                                                                                                                                                                                   |
| <b>ClimeDoc to achieve SDGs</b>                                                          | A documentary on impacts of climate change significantly contributes promotion of appropriate actions to achieve SDGs in developing nations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| <b>Waste, a source of resource-learn to empower</b>                                     | This project utilizes poor women affected by dumped waste by providing earning source at the same time preventing production greenhouse gas.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Living Energy - connecting science, design and nature to light up our world</b>      | Living Light is an atmospheric lamp which harvests its energy from the plant living next to the lamp itself. The light of the lamp is produced by 'plant microbial fuel cell technology': energy generated by bacteria in the soil which release electrons while breaking down organic compounds of the plant. These collected electrons, for which we have created a storage mechanism, produce enough energy to light up the LED lights for about an hour in the current phase of development. Because the Living Light symbolises an extra-ordinary lamp, we have given it an extra-ordinary switch: by softly stroking the leaves transforms this ordinary plant into a Living Light. |
| <b>An environmental conservation approach to handling oil and gas in Uganda</b>         | Development of oil deposits in an environmentally conscious manner                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Land for life: an alternative to slash-and-burn in the world's rain forests</b>      | "Guama", an integrated agroforestry model, is transforming family livelihoods, saving rain forests; restoring degraded soils and landscapes                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Population control</b>                                                               | Population control solves EVERY identified problem facing humanity. You don't get more synergistic than that.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Potential for zeolites for conserving moisture in drought prone areas of Africa</b>  | Moisture conserving ability of Zeolite minerals can be exploited to enhance crop and tree production in drought prone areas of Africa.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Leveraging telecommunication for decoupling SDGs using a whole systems approach</b>  | Building an ICT-led citizen movement to address some of the Sustainable Development Goals and climate action from the bottom up.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Adapting the indigenous approach to climate change adaptation and mitigation</b>     | The project is dedicated to emphasizing the indigenous adaptation and mitigation techniques adapted by local communities in responding to climate change issues.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Solar based poly-generation system that can provide power, heat, and clean water</b> | Our system uses Solar concentrators to provide Power, Heat and clean water at 1/3rd the capital cost of SolarPV and has no disposable costs.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

## The GEO-6 Process

*"We all share one planet and are one humanity;  
there is no escaping this reality."*

*Wangari Maathai (1940-2011), Nobel Laureate*

## Objectives, Scope and Process

The Mandate for the sixth Global Environment Outlook was obtained from Member States at the first UN Environment Assembly (resolution 1/4, operative paragraph 8). More information on this mandate can be found in Annex 1-1 of this report. The objectives, scope and process for GEO-6 were defined and adopted in a Final Statement by the Global Intergovernmental and Multi-Stakeholder Consultation that took place in October 2014. It was attended by more than 133 delegates with more than 100 governments represented.

### Objectives

The consultation reaffirmed the UNEA-1 mandate by identifying the following objectives for the assessment:

- ❖ provide a comprehensive, integrated and scientifically credible global environmental assessment to support decision-making processes at appropriate levels;
- ❖ facilitate broader participation by major groups and stakeholders, in particular from the private sector and NGOs and to increase outreach to target audiences;
- ❖ The analysis should draw on diverse knowledge systems, including by using accepted guidelines for the use of peer reviewed scientific literature, grey literature, data and indigenous and local knowledge;
- ❖ A clear process and organizational structure is needed to ensure credibility, legitimacy and relevance;
- ❖ "The assessment should build on and be consistent with previous GEOs, as well as the work of other relevant intergovernmental organizations and processes, including Multilateral Environmental Agreements, in order to maintain its branding and role in keeping the environmental situation under review";<sup>1</sup>
- ❖ inform, as appropriate, the strategic directions of UNEP and other relevant UN bodies;
- ❖ strengthen the policy relevance of GEO-6 by including an analysis of case studies of policy options, that incorporates environmental, economic, social and scientific data and information and their indicative costs and benefits to identify promising policy options to speed up achievement of the internationally agreed goals such as the Sustainable Development Goals and other multilateral environmental agreements;
- ❖ identify data gaps in the thematic issues considered by GEO-6.

### Scope

GEO-6 builds on previous GEO reports and continues to provide an analysis of the state of the global environment, the global, regional and national policy response as well as the outlook for the foreseeable future. It differs from previous GEO reports in its emphasis on Sustainable Development Goals and in providing possible means of accelerating achievement of these goals. GEO-6 is made up of four distinct but closely linked parts.

- ❖ **Part A** assesses the state of the global environment in relation to key internationally agreed goals such as the

Sustainable Development Goals and those of various multilateral environmental agreements. The assessment is based on national, regional and global analyses and datasets.

- ❖ **Part B** provides an analysis of the effectiveness of the policy response to these environmental challenges as well as an analysis of progress towards achieving specific environmental goals.
- ❖ **Part C** reviews the scenarios literature and assesses pathways towards achieving Agenda 2030 as well as achieving a truly sustainable world in 2050.
- ❖ **Part D** identifies future data and knowledge necessary to improve our ability to assess environmental impacts and pathways for achieving sustainability.

The GEO-6 also considers key policy questions. These include:

- ❖ What are the primary drivers of environmental change?
- ❖ What is the current state of the environment and why?
- ❖ How successful have we been in achieving our internationally agreed environmental goals?
- ❖ Have there been successful environmental policies?
- ❖ What are the policy lessons learned and possible solutions?
- ❖ Is the current policy response enough?
- ❖ What are the business as usual scenarios and what does a sustainable future look like?
- ❖ What are the emerging issues and megatrends including their possible impacts?
- ❖ What are the possible pathways to achieving Agenda 2030 and other internationally agreed environmental goals?

### Process

The October 2014 consultation also provided direction for strengthening the process of the GEO-6 assessment, including:

- ❖ The assessment process shall be supported by two main advisory bodies: the High-level Intergovernmental and Stakeholder Advisory Group (HLG) and the Scientific Advisory Panel (SAP);
- ❖ Advice shall also be obtained from an Assessment Methodologies, Data and Information Working Group;
- ❖ Other GEO-6 roles would include: Coordinating Lead Authors (CLAs); Lead Authors; up to 20 GEO-6 Fellows and Coordinators; global experts; regional experts; community of practice moderators; review editors; and reviewers;
- ❖ the CLAs will provide technical summaries of the GEO 6 and prepare the negotiating drafts of the Summary for Policymakers in close collaboration with and under the leadership of the HLG, ensuring that the technical aspects of GEO-6 are reflected in the draft. The SPM would be negotiated at a dedicated intergovernmental and stakeholder meeting;
- ❖ Relevant MEAs, international organizations and scientific institutions will be invited to actively contribute to the GEO-6 process.
- ❖ The GEO-6 will ensure scientific credibility, policy relevance and legitimacy of the assessment by engaging a wide range of stakeholders;
- ❖ The assessment will be subjected to extensive scientific expert peer review and government review;

<sup>1</sup> Outcomes document of the Intergovernmental and Multi-stakeholder consultation, 21-23 October, 2014, Berlin, Germany. The full text of the Outcomes document can be found in the Appendix to this section.

- ❖ The assessment process will continue to target institutional capacity building by engaging developing country experts;
- ❖ The assessment should strive to communicate key messages and findings to target audiences in an accessible manner.

## TIMELINE

The sixth Global Environment Outlook process was characterized by 4 larger authors meetings, two smaller drafting meetings on Outlooks and Policy, as well as face to face meetings of the advisory bodies, Review Editors and Member States. The meeting and drafting schedule followed 3 basic principles established by the advisory bodies:

- ❖ There should be coherence across the different Parts of GEO-6 and the 12 cross-cutting issues should be drafted in tandem with the assessment of the 5 environmental themes.
- ❖ There should be opportunities for robust interaction between the authors and the advisory bodies to ensure both policy relevance and scientific integrity are maintained throughout the process.
- ❖ The author teams should be kept small since the regional assessments contain much of the information that is needed in the global assessment and they should form the foundation of the global assessment.

To ensure robust interaction with the advisory bodies, 3 of the 4 larger authors meetings had participation from the High-level Group and the Scientific Advisory Panel. To ensure coherence

across the assessment, the larger meetings were used to allow for 'speed dating' between the thematic chapter authors and the cross-cutting issue authors. This 'speed dating' allowed for 1 hour of discussion between the authors teams where issues were discussed and writing assignments given. To ensure that the author teams were kept small, a core of coordinating lead authors were first selected into the process and then skills gaps were identified. From the skills gap analysis, invitations were sent to lead authors to complement the drafting of the chapters.

As the work programme evolved it became clear that additional authors meetings for the Policy and Outlooks chapters would be needed. The Secretariat proceeded to organize these during the months of May and June, 2018. In addition, the Scientific Advisory Panel requested to meet one last time in order to formulate their opinion on the scientific credibility of the GEO process. This meeting was organized back-to-back with the final Review Editors meeting in October, 2018. This allowed for the two groups to share information about the peer review processes and their overall rigour.

The drafting meeting for the Summary for Policymakers involved the High-level Group, Coordinating Lead Authors as well as the Co-chairs of the assessment. The Co-chairs of the Scientific Advisory Panel also participated as observers and provided some of their experience with drafting of Summaries in other assessment processes.

The final meeting of the GEO process was the meeting of Member States to finalize and adopt the Summary for Policymakers. This meeting was held at UN Environment headquarters which allowed for a broad participation of

Member States. The 4-day meeting sought to review the text of the Summary and make changes that would allow for its adoption by all Member States present. The final adopted document was submitted to the fourth UN Environment Assembly for endorsement.

## PARTNERSHIPS AND COLLABORATION

The development of GEO-6 involved extensive collaboration both within UN Environment and between UN Environment and a network of multidisciplinary experts and research institutions, all of whom made their valuable time and knowledge available to the process.

The consultation requested that experts for content development, including reviewers and advisory groups, be nominated by governments and other main stakeholders based on their expertise and using a transparent nomination process. The nominated experts were then convened by the UN Environment Secretariat based on their expertise with due consideration of gender and regional balance.

### Chapter expert groups

The GEO-6 report contains 25 chapters. An expert author group was established for each chapter to conceptualize, research, draft, revise and finalize each chapter. More than 150 authors and fellows were involved in content development. Each chapter expert was under the leadership of three or four coordinating lead authors and supported by a UN Environment chapter coordinator. Other members of the chapter expert groups comprised lead authors and contributing authors.

## GEO-6 fellows

GEO-6 continued to pursue the Fellowship initiative established during the GEO-4 process in 2005. This engages early career professionals in the GEO process so that they can gain experience from participating in a major global environmental assessment. A total of 27 fellows from 15 countries participated in GEO-6.

## REVIEW PROCESS

The GEO-6 assessment underwent five rounds of review involving more than 1000 experts. In total the GEO-6 assessment was reviewed five times at different stages of its development and the process yielded more than 14,000 comments. Due to this process, the draft chapters have been re-written, adjusted and edited to improve the quality while the drafting process has been adjusted to improve its effectiveness.

The first nine introductory chapters of the assessment: introduction, drivers of environmental change, state of our data and knowledge, the crosscutting chapter as well as the state of the global environment, across 5 main thematic areas: air, biodiversity, oceans, land and freshwater were reviewed earlier in the process than the policy and outlooks chapters. At the end of the review process all chapters were provided for review by technical experts then for a longer intergovernmental and expert review. For the final review the chapters were provided as individual chapters (25 chapters separately) and as a complete assessment report (all chapters as a single document). This offered reviewers an opportunity to either

review specific chapters that were directly related to their areas of expertise or review the whole assessment report to comment on the report's coherence.

For all review periods the secretariat offered a 'service desk' where all reviewers with questions or concerns were supported in this task. Virtual meetings were organized for all reviewers coordinated by the secretariat to first orient the review team before the start of the review process and then to check on progress as well as answer questions. These virtual meetings were conducted by the secretariat with support from the lead review editors, who listened in and provided advice on any issues. The preparatory review material/tools were discussed during these meetings with the concentration being on the reviewer's guidelines. Terms of reference for the reviewers were developed and updated for each review period, including the ethical responsibilities of GEO-6 Reviewers. During the review period the secretariat conducted follow-up calls for all available reviewers to assess the progress and review important deadlines. All review call recordings were shared with the whole review team to ensure that other reviewers were aware of the tasks and the plan for moving forward.

## **GEO-6 ADVISORY BODIES**

Three external specialized advisory bodies were established to support the assessment process.

### **High-Level Intergovernmental and Stakeholder Advisory Group**

The panel included 33 high-level government representatives from all six UN Environment regions as well as 8-10 key stakeholders. The High-level Group assessed and formulated strategic advice to GEO-6 authors and other groups to assist them in their assessment work. They also provided initial guidance on the structure and content of the GEO-6 Summary for Policymakers and further guidance to the experts in finalizing the draft Summary, in preparation for the final intergovernmental negotiation. In addition, ad-hoc guidance was provided to UN Environment throughout the assessment process to align the GEO-6 process with other relevant global assessments. The High-level Group met face-to-face seven times between 2015 and 2018. The Advisory Group also met virtually on a monthly basis throughout the preparation of the global assessment, from May 2016 to September 2018.

### **Science Advisory Panel**

The Panel included 22 distinguished scientists who met face-to-face five times. The Panel was responsible for providing advice on the scientific credibility of the assessment process. The Panel provided scientific advice; standards and guidelines for the assessment and review process; and reviewed the findings of the mid-term evaluation of the assessment process. The Panel met virtually on a monthly basis throughout the preparation of the global assessment, from June 2016 to October 2018.

### **Assessment Methodologies, Data and Information Working Group**

The working group comprised of 12 professionals who met face-to-face three times between 2015 and 2018 and provided support to the assessment process and provide guidance on the use of core datasets and indicators. They consulted with experts to review the methods used in GEO-6, identify priority environmental indicators as well as data gaps and related issues. The Working Group met virtually as needed throughout the process.

## **CONSULTATION PROCESS**

UNEP organized panel discussions at all authors meetings throughout the assessment process. These panel discussions were intended to delve into specific environmental issues that were relevant to the region and location of the meeting. The following are some of the key meetings convened since the inception of the GEO-6 process.

### **GEO-6 planning meetings**

Two planning meetings were convened with the High-level Group and the Scientific Advisory Panel May and June 2016. The meetings produced a final annotated outline for the global assessment and a list of recommended co-chairs and coordinating lead authors.

### **Global Intergovernmental and Multi-stakeholder Consultation**

This consultation defined and adopted the scope, objectives and process for GEO-6 in October 2014. Participants at the Intergovernmental and Multi-Stakeholder Consultation concluded that GEO-6 would be an integrated environmental assessment using the Drivers – Pressures – State – Impacts – Response (DPSIR) approach. The report would build on regional assessments and include an inter-governmentally negotiated Summary for Policymakers. The analysis would aim to present findings and deliver products to targeted audiences including decision makers, across the public and private sectors, such as businesses and the youth.

### **Outlooks expert meeting**

In May 2018, an outlooks expert group, was convened to move the policy chapters to third order draft quality by addressing all comments from the science editors, as well as comments received from the second order draft technical review period.

### **Policy expert meeting**

In June 2018, a policy expert group, was convened to move the policy chapters to third order draft quality by addressing all comments from the science editors, as well as comments received from the second order draft technical review period.

#### **Global authors' meetings**

Four global production and authors' meetings were convened in February 2017, May 2017, October 2017 and in February 2018 to discuss and develop GEO-6-chapter content and outlines, to address review comments, and to harmonize different approaches and presentation styles.

#### **Chapter working group meetings**

Hundreds of virtual chapter meetings were convened to prepare, review and revise the drafts for individual chapters.

#### **Summary for Policymakers intergovernmental meeting**

A final open-ended intergovernmental meeting was convened from January 21-24, 2019 in Nairobi, Kenya to negotiate and adopt the GEO-6 Summary for Policymakers (SPM). The

meeting attended by 95 Governments adopted the summary, which presents the policy-relevant findings of GEO-6 and is published as a separate document. The GEO-6 Summary for Policymakers was presented to the fourth UN Environment Assembly for endorsement.

The launch of GEO-6 will coincide with the fourth United Nations Environmental Assembly. GEO-6 highlights the current state, trends and outlook for the planet and its people, and showcases more than 35 case studies of policies that have been assessed for their effectiveness.

GEO-6 highlights not just the perils of delaying action, but the options for transforming our economic, environmental and social systems to achieve a truly sustainable world.

## Appendix

Statement by the Global Intergovernmental and Multi-stakeholder Consultation on the Sixth Global Environment Outlook held in Berlin from 21 – 23 October 2014

### UNEP/IGMC.2 Rev.2

#### Strengthening the Science Policy Interface:

#### Building the Evidence Base for the Post-2015 Agenda

23 October 2014

#### Organisation of work

The Global Intergovernmental Multi-stakeholder Consultation (IGMS) met in Berlin from 21-23 October 2014. It was attended by 133 delegates, with more than 100 governments represented.

The meeting was opened by Achim Steiner, Executive Director of UNEP.

The election of officials followed. Idunn Eidheim (Norway) and Dr. Majid Shafie-Pour (Iran) were elected Co-Chairs. Dr. Peter Denton (Major Groups and Stakeholders) was elected Rapporteur.

#### Background

Reference was made to the Rio+20 outcome document, earlier Governing Council decisions, and specifically to UNEA Resolutions 4 and 10.

The Secretariat presented the recommendations of the independent evaluation of GEO-5 which stated the need to:

*“(1) facilitate stakeholder engagement; (2) enhance capacity building; (3) increase the use of grey literature and indigenous knowledge; (4) promote relevance at all scales; (5) increase developing country participation; (6) facilitate access to information; (7) use results based management and evidence for evaluations; and (8) improve financial planning and funding.”*

Participants at the IGMS noted the findings of the evaluation and expressed the need to facilitate broader participation by major groups and stakeholders, in particular from the private sector and NGOs and to increase outreach to target audiences. The analysis should draw on diverse knowledge systems, including by using accepted guidelines for the use of peer reviewed scientific literature, grey literature, data and indigenous and local knowledge. A clear process and organizational structure is needed to ensure credibility, legitimacy and relevance. The assessment should build on and be consistent with previous GEOs, as well as the work of other relevant intergovernmental organizations and processes including such as MEAs, in order to maintain its branding and role in keeping the environmental situation under review.

Under Agenda Item Four, the meeting participants discussed options and timing for GEO-6.

#### Structure for the content of GEO-6

Participants at the IGMS supported that GEO-6 would be an integrated environmental assessment, using the Drivers – Pressures – State – Impacts – Response (DPSIR) approach in the GEO conceptual framework. The Report will build on regional assessments and include an inter-governmentally negotiated Summary for Policymakers. The analysis will aim at presenting findings and delivering products to targeted audiences among decision makers, across the public and private sectors at global to local levels.

GEO-6 will reflect three broad, analytical components.

#### Global Environment: State and Trends

The first component will include an analysis of the environmental state and trends for air, biota, land and water and their multiple contributions to environment and human well-being. This will be achieved through an analysis of interactions with cross-cutting issues such as climate change; environmental disasters; food; energy; human health; economic development; resource use; chemicals and waste; and culture and society, and relevant policies.

#### Environmental Policies, Goals and Objectives: A Review of Policy Responses and Options

The second component will provide a policy analysis of the links between the state and trends in the environment and global and regional environmental goals and objectives, including those reflected in national policy responses, and an assessment of progress towards them.

#### Global Environment Outlook

The third component will be comprised of an integrated analysis of megatrends and environmental change, and refer to the outputs of modeling, scenarios and regional outlooks. The analysis will take into account the Global Sustainable Development Report and provide support to the environmental components of the post-2015 agenda.

#### Timing of GEO-6

Participants expressed broad support for the following delivery dates: GEO-6 regional assessments to be delivered by early 2016 and the complete GEO-6 including its Summary for Policymakers to be delivered not later than 2018, at an appropriate event to be determined in consultation between UNEP and governments. Regional assessments will be undertaken during 2015. The Executive Director of UNEP will report on progress to UNEA 2 in 2016.

#### Process and operational structure of GEO-6

Participants also voiced support for the establishment of two advisory bodies: the High-level Intergovernmental and Stakeholder Advisory Group (HLG) and the Scientific Advisory Panel (SAP). There will also be an Assessment Methodologies, Data and Information Working Group. The HLG will include five representatives from each UN region, plus five representatives from the Major Groups and Stakeholders. The SAP will be comprised of three representatives from each UNEP region,

plus up to six global experts. The Assessment Methodologies, Data and Information Working Group will be comprised of three representatives from each UNEP region, plus up to six global experts. Participants expressed a wish to include individuals with indigenous and local knowledge.

Other GEO-6 roles would include: Coordinating Lead Authors (CLAs); Lead Authors; up to 20 GEO-6 Fellows; Global Experts; Regional Experts; Community of Practice Moderators; Review Editors; and Reviewers.

The participants discussed the terms of reference for the operational structure as set out in the Annex 1.

Based on practice from earlier GEOs and other international scientific assessments, the CLAs will provide technical summaries of the GEO 6 and preparing the negotiating drafts of the Summary for Policymakers in close collaboration with and under the leadership of the HLG, ensuring that the technical aspects of GEO-6 are reflected in the draft. The SPM would be negotiated at a dedicated intergovernmental and stakeholder meeting.

It was noted that UNEP Live will be used by the Secretariat to enhance capacity development and to support GEO-6 by providing the platform for the GEO-6 Communities of Practice and the Nominations Portal. UNEP Live will also support the global and regional analyses through relevant data collection related to *inter alia* UNSEEA and indicator development; encouraging sharing and access to national data and information; linking to peer-reviewed literature from various language domains; providing access to indigenous and local knowledge and information drawn from attributable, public sources. Information should also be provided on the benefits of UNEP Live for countries; the roles of MEAs in UNEP Live and on the UNEP Live programme of work.

Support was given for the GEO-6 to use Communities of Practice to encourage sharing of knowledge amongst the various groups, increase stakeholder engagement and support capacity development. CoPs will be established for the major areas of GEO-6 and regional assessments. Capacity development would be supported through the fellowship programme, the implementation of national reporting systems, along with participation in regional environmental information networks and regional assessments.

Relevant MEAs, international organizations and scientific institutions will be invited to actively contribute to the GEO-6 process.

Support was given for the multi-stage peer review, based on the following principles. First the best possible scientific and technical advice should be included to ensure that the assessment represents the latest scientific, technical and socioeconomic findings and is as comprehensive as possible. Second, a broad circulation process ensuring representation of experts not involved in the preparation of the parts they are reviewing, with particular emphasis on involving as many experts from developing countries as possible. Third, the peer-review by governments will include both technical and policy aspects with due respect to the independence of the reviewers. Finally, the multi-stage review process to be balanced, open and transparent. Conflicts of interest will be identified through a process based on those used by IPBES and IPCC.

### Nomination process

Participants emphasized the need for an open and transparent nomination process for all the GEO-6 roles, using the GEO-6 Nominations Portal in UNEP Live. The experts will be nominated using the criteria outlined in Annex II, and be selected by UNEP in a transparent manner with due consideration of the need to ensure geographic, disciplinary and gender balance. The nomination period will run until January 31, 2015. The selection process will be completed by the end of February 28, 2015. Late nominations will be accepted under mitigating circumstances. The selected experts and nominees for the advisory bodies will be sent to governments for review. The list of selected experts will be published on-line.

Governmental representatives for the HLG must be nominated by their respective governments and will act in this capacity. The selection process for the stakeholder representatives will be overseen by the UNEP Major Groups and Stakeholders Branch. The selection procedure for the HLG will be determined within the UN regional groups.

The nomination process will be initiated by a letter from the Secretariat to be sent to governments and Major Groups and Stakeholders. This correspondence will be in the relevant UN language and append details of the GEO-6 processes, including remuneration of experts and a GEO-6 timetable.

## Contributors

### GEO-6 Author teams

**Co- chairs:** Paul Ekins [University College London, United Kingdom of Great Britain and Northern Ireland]; Joyeeta Gupta [University of Amsterdam, The Netherlands].

**Vice- chairs:** Jane Bemigisha [ESIPPS International Ltd, Uganda]; Kejun Jiang [Energy Research Institute, China].

#### Chapter 1 Introduction and Context:

Mark Elder [Institute for Global Environmental Strategies, Japan]; Christian Loewe [German Environment Agency, Germany].

#### Chapter 2 Drivers of Environmental Change:

Tariq Banuri [University of Utah, United States of America]; Matthew Kosko (GEO Fellow) [University of Utah, United States of America]; Diego Martino [AAE Asesoramiento Ambiental Estratégico and ORT University, Uruguay]; Indu K. Murthy [Indian Institute of Science, India]; Jacob Park [Green Mountain College, United States of America]; Fernando Filgueira Prates [Centro de Informaciones y Estudios del Uruguay (CIESU), Uruguay]; Maria Jesus Iraola Trambauer (GEO Fellow) [University College London (UCL), United Kingdom of Great Britain and Northern Ireland]; Dimitri Alexis Zenghelis [London School of Economics, United Kingdom of Great Britain and Northern Ireland].

#### Chapter 3 The State of Our Data and Knowledge:

Graeme Clark [University of New South Wales, Australia]; Florence Mayocycoc-Daguitan [Tebtebba (Indigenous Peoples' International Centre for Policy Research and Education), Philippines]; James Donovan [ADEC Innovations, United Kingdom of Great Britain and Northern Ireland]; Pali Lehohla [Pan African Institute for Evidence, South Africa]; Sheryl Joy Anne S. Gutierrez [ADEC Innovations, Philippines]; Charles Mwangi [GLOBE Program Kenya]; Amit R. Patel (GEO Fellow) [Planned Systems International Inc., United States of America]; Joni Seager [Bentley University, United States of America]; William Sonntag [The Group on Earth Observation Secretariat, United States of America]; Michelle Tan [ADEC Innovations, Kenya].

#### Chapter 4 Cross-cutting Issues:

Babatunde Joseph Abiodun [University of Cape Town, South Africa]; Giovanna Armiento [ENEA - Italian National Agency for New Technologies, Energy and Sustainable Economic Development, Italy]; Rob Bailey [Chatham House, The Royal Institute of International Affairs, United Kingdom of Great Britain and Northern Ireland]; Rajasekhar Balasubramanian [National University of Singapore, Singapore]; Ricardo Barra [University of Concepcion, Chile]; Kathryn Jennifer Bowen [Australian National University, Australia]; John Crump [GRID-Arendal, Norway]; Irene Dankelman [Radboud University, Netherlands]; Kari De Pryck (GEO Fellow) [SciencesPo, France]; Riyanti Djalante [United Nations University – Institute for the Advanced Study of Sustainability, Japan]; Monica Dutta

[The Energy and Resources Institute (TERI), India]; Francois Gemenne [The Hugo Observatory, Université de Liège, Belgium]; Linda Godfrey [Council for Scientific and Industrial Research (CSIR), South Africa]; James Grellier [University of Exeter, United Kingdom of Great Britain and Northern Ireland]; Maha Halalsheh [University of Jordan, Jordan]; Fintan Hurley [Institute of Occupational Medicine, United Kingdom of Great Britain and Northern Ireland]; Richard King [Chatham House, The Royal Institute of International Affairs, United Kingdom of Great Britain and Northern Ireland]; Andrei P. Kirilenko [University of Florida, United States of America]; Peter Lemke [Alfred-Wegener-Institut, Germany]; Daniela Liggett [University of Canterbury, New Zealand]; Robyn M. Lucas [National Centre for Epidemiology and Population Health, The Australian National University, Australia]; Oswaldo Lucon [Sao Paulo State Environment Secretariat, Brazil]; Katrina Lyne (GEO Fellow) [James Cook University, Australia]; Diego Martino [AAE Asesoramiento Ambiental Estratégico and ORT University, Uruguay]; Ritu Mathur [The Energy and Resources Institute (TERI), India]; Shanna N. McClain [Environmental Law Institute, United States of America]; Catherine P. McMullen, Stockholm Environment Institute -Asia Centre, Thailand]; Emma Gaalaas Mullaney [Bucknell University, United States of America]; Unai Pascual [Ikerbasque, the Basque Foundation for Science, Spain]; Leisa N. Perch [SAEDI Consulting, Trinidad and Tobago]; Marco Rieckmann [University of Vechta, Germany]; Fülöp Sándor [National University of Public Services, Hungary]; Atilio Savino [ARS, Argentina]; Heinz Schandl [Commonwealth Scientific and Industrial Research Organisation (CSIRO), Australia]; Joeri Scholtens [University of Amsterdam, Netherlands]; Patricia Nayna Schwerdtle (GEO Fellow) [Monash University, Australia]; Joni Seager [Bentley University, United States of America]; Lei Shi [Tsinghua University, China]; Frank Thomalla [Stockholm Environment Institute - Asia Centre, Thailand]; Maria Jesus Iraola Trambauer (GEO Fellow) [University College London (UCL), United Kingdom of Great Britain and Northern Ireland]; Laura Wellesley [Chatham House, The Royal Institute of International Affairs, United Kingdom of Great Britain and Northern Ireland]; Caradee Y. Wright [South African Medical Research Council, South Africa]; Dan Wu [Sun Yat-Sen University, China]; Dimitri Alexis Zenghelis [London School of Economics, United Kingdom of Great Britain and Northern Ireland]; Caroline Zickgraf [The Hugo Observatory, Université de Liège, Belgium].

#### Chapter 5 State of the Global Environment: Air:

Babatunde Joseph Abiodun [University of Cape Town, South Africa]; Kathryn Jennifer Bowen [Australian National University, Australia]; Serena H. Chung [U.S. Environmental Protection Agency, United States of America]; Phillip Dickerson [U.S. Environmental Protection Agency, United States of America]; Riyanti Djalante [United Nations University – Institute for the Advanced Study of Sustainability, Japan]; Cristina de B. B. Guerreiro [Norwegian Institute for Air Research – NILU, Portugal]; Chenmin He (GEO Fellow) [Peking University, China]; Fintan Hurley [Institute of Occupational Medicine, United Kingdom of Great Britain and Northern Ireland]; Terry Keating [U.S. Environmental Protection Agency, United States of America]; Andrei P. Kirilenko [University of Florida, United States of America]; Robyn M. Lucas [National Centre for Epidemiology

and Population Health, The Australian National University, Australia]; John Muthama Nzioka [University of Nairobi, Kenya]; Stefan Reis [Centre for Ecology and Hydrology, United Kingdom of Great Britain and Northern Ireland]; Caradee Y. Wright [South African Medical Research Council, South Africa].

### Chapter 6 Biodiversity:

Rob Bailey [Chatham House, The Royal Institute of International Affairs, United Kingdom of Great Britain and Northern Ireland]; Colin Butler [University of Canberra, Australia]; Irene Dankelman [Radboud University]; Jonathan Davies [University of British Columbia, United Kingdom of Great Britain and Northern Ireland]; Linda Godfrey [Council for Scientific and Industrial Research (CSIR), South Africa]; Jeremy Hills [The University of the South Pacific, United Kingdom of Great Britain and Northern Ireland]; Andrei P. Kirilenko [University of Florida, United States of America]; Daniela Liggett [University of Canterbury, New Zealand]; Louise McRae [Institute of Zoology, Zoological Society of London, United Kingdom of Great Britain and Northern Ireland]; Gavin Mudd [RMIT University, Australia]; Dolors Armenteras Pascual [Universidad Nacional de Colombia, Colombia]; Joni Seager [Bentley University, United States of America]; Peter Stoett [University of Ontario Institute of Technology, Canada]; Carol Zastavniouk (GEO Fellow) [Golder Associates, Canada]; Caroline Zickgraf [The Hugo Observatory, Université de Liège, Belgium].

### Chapter 7 Oceans and Coasts:

AlAnoud Alkhatlan (GEO Fellow) [Arabian Gulf University, Bahrain]; Elaine Baker [GRID-Arendal at the University of Sydney, Australia]; James Grellier [University of Exeter, United Kingdom of Great Britain and Northern Ireland]; Peter Harris [GRID-Arendal, Norway]; Adelina Mensah [Institute for Environment and Sanitation Studies - University of Ghana, Ghana]; Jake Rice [Department of Fisheries and Oceans Canada – Emeritus, Canada].

### Chapter 8 Land and Soil:

Nicolai Dronin [Moscow State University, Russian Federation]; Andrés Guhl [Universidad de los Andes, Colombia]; Gensuo Jia [Chinese Academy of Sciences, China]; Javier Naupari [Universidad Nacional Agraria La Molina, Peru]; Darshini Ravindranath (GEO Fellow) [University College London (UCL), United Kingdom of Great Britain and Northern Ireland]; Hung Vo (GEO Fellow) [Harvard Graduate School of Design, United States of America]; Ying Wang (GEO Fellow) [Tongji University, China].

### Chapter 9 Freshwater:

Erica Gaddis [Utah Department of Environmental Quality, United States of America]; Anna Maria Grobicki [Food and Agriculture Organization, Italy]; Rowena Hay [Umvoto, South Africa]; Gavin Mudd [RMIT University, Australia]; Walter Rast [Meadows Center for Water and Environment - Texas State University, United States of America]; Jaee Sanjay Nikam [Arizona State University, United States of America]; Beatriz Rodríguez-Labajos (GEO Fellow) [Universitat Autònoma de Barcelona, Spain]; Ying Wang [Tongji University, China].

### Chapter 10 Approach to Assessment of Policy Effectiveness:

Klaus Jacob [Freie Universität Berlin, Germany]; Peter King [Institute for Global Environmental Strategies, Thailand]; Diana Mangalagiu [University of Oxford and Neoma Business School, United Kingdom of Great Britain and Northern Ireland]; Beatriz Rodríguez-Labajos (GEO Fellow) [Universitat Autònoma de Barcelona, Spain].

### Chapter 11 Policy Theory and Practice:

Pedro Fidelman [Centre for Policy Futures, The University of Queensland, Australia]; Leandra Regina Gonçalves [University of Campinas/Center for Environmental Studies and Research (NEPAM), Portugal]; Chenmin He (GEO Fellow) [Peking University, China]; James Hollway [Graduate Institute of International and Development Studies, Switzerland]; Klaus Jacob [Freie Universität Berlin, Germany]; Peter King [Institute for Global Environmental Strategies, Thailand]; Sebastian Sewerin [Swiss Federal Institute of Technology Zurich (ETH Zurich), Switzerland].

### Chapter 12 Overview of Air Policy Instruments:

Frederick Ato Armah [University of Cape Coast, Ghana]; Kari De Pryck (GEO Fellow) [SciencesPo, France]; Phillip Dickerson [U.S. Environmental Protection Agency, United States of America]; Cristina de B. B. Guerreiro [Norwegian Institute for Air Research – NILU, Norway]; Terry Keating [U.S. Environmental Protection Agency, United States of America]; Peter King [Institute for Global Environmental Strategies, Thailand]; Oswaldo Lucon [Sao Paulo State Environment Secretariat, Brazil]; Asami Miyazaki [Kumamoto Gakuen University, Japan]; Amit R. Patel (GEO Fellow) [Planned Systems International Inc., United States of America]; Stefan Reis [Centre for Ecology and Hydrology, United Kingdom of Great Britain and Northern Ireland].

### Chapter 13 Biodiversity Policy:

Irene Dankelman [Radboud University, Netherlands]; Jonathan Davies [University of British Columbia, United Kingdom of Great Britain and Northern Ireland]; Leandra Regina Gonçalves [University of Campinas/Center for Environmental Studies and Research (NEPAM), Portugal]; Souhir Hammami (GEO Fellow) [Freie Universität Berlin, Germany]; Jeremy Hills [The University of the South Pacific, Fiji]; Diana Mangalagiu [University of Oxford and Neoma Business School, United Kingdom of Great Britain and Northern Ireland]; Louise McRae [Institute of Zoology, Zoological Society of London, United Kingdom of Great Britain and Northern Ireland]; Nibedita Mukherjee [University of Cambridge, United Kingdom of Great Britain and Northern Ireland]; Dolors Armenteras Pascual [Universidad Nacional de Colombia, Colombia]; Peter Stoett [University of Ontario Institute of Technology, Canada]; Caradee Y. Wright [South African Medical Research Council, South Africa]; Carol Zastavniouk (GEO Fellow) [Golder Associates, Canada].

### Chapter 14 Oceans and Coastal Policy:

AlAnoud Alkhatlan (GEO Fellow) [Arabian Gulf University, Bahrain]; Elaine Baker [GRID-Arendal at the University of Sydney, Australia]; Pedro Fidelman [Centre for Policy Futures, The University of Queensland, Australia]; Leandra Regina Gonçalves

[University of Campinas/Center for Environmental Studies and Research (NEPAM), Portugal]; Peter Harris [GRID-Arendal, Norway]; James Hollway [Graduate Institute of International and Development Studies, Switzerland]; Rakhyun E. Kim [Utrecht University, Netherlands]; Diana Mangalagiu [University of Oxford and Neoma Business School, United Kingdom of Great Britain and Northern Ireland]; Jake Rice [Department of Fisheries and Oceans Canada – Emeritus, Canada].

#### Chapter 15 Land and Soil Policy:

Katharina Helming [Leibniz Centre for Agricultural Landscape Research (ZALF), Germany]; Klaus Jacob [Freie Universität Berlin, Germany]; Peter King [Institute for Global Environmental Strategies, Thailand]; Diana Mangalagiu [University of Oxford and Neoma Business School, United Kingdom of Great Britain and Northern Ireland]; Andrew Onwuemele [Nigerian Institute of Social and Economic Research (NISER), Nigeria]; Darshini Ravindranath (GEO Fellow) [University College London (UCL), United Kingdom of Great Britain and Northern Ireland]; Hung Vo (GEO Fellow) [Harvard Graduate School of Design, United States of America]; Leila Zamani (GEO Fellow) [Department of Environment Islamic Republic of Iran, Iran (Islamic Republic of)]; Pandi Zdruli [Mediterranean Agronomic Institute of Bari (CIHEAM), Italy].

#### Chapter 16 Freshwater Policy:

Erica Gaddis [Utah Department of Environmental Quality, United States of America]; James Grellier [University of Exeter, United Kingdom of Great Britain and Northern Ireland]; Anna Maria Grobicki [Food and Agriculture Organization, Italy]; Rowena Hay [Umvoto, South Africa]; Peter King [Institute for Global Environmental Strategies, Thailand]; Naho Mirumachi [King's College London, United Kingdom of Great Britain and Northern Ireland]; Gavin Mudd [RMIT University, Australia]; Farhad Mukhtarov [International Institute of Social Studies, Erasmus University Rotterdam, Netherlands]; Jaee Sanjay Nikam [Arizona State University, United States of America]; Walter Rast [Meadows Center for Water and Environment - Texas State University, United States of America]; Beatriz Rodríguez-Labajos (GEO Fellow) [Universitat Autònoma de Barcelona, Spain]; Patricia Nayna Schwerdtle (GEO Fellow) [Monash University, Australia].

#### Chapter 17 Systemic Policy Approaches for Cross-cutting Issues:

Babatunde Joseph Abiodun [University of Cape Town, South Africa]; Giovanna Armiento [ENEA - Italian National Agency for New Technologies, Energy and Sustainable Economic Development, Italy]; Rob Bailey [Chatham House, The Royal Institute of International Affairs, United Kingdom of Great Britain and Northern Ireland]; Elaine Baker [GRID-Arendal at the University of Sydney, Australia]; Kathryn Jennifer Bowen [Australian National University, Australia]; John Crump [GRID-Arendal, Norway]; Irene Dankelman [Radboud University, Netherlands]; Riyanti Djalante [United Nations University – Institute for the Advanced Study of Sustainability, Japan]; Monica Dutta [The Energy and Resources Institute (TERI), India]; Fintan Hurley [Institute of Occupational Medicine, Ireland]; Klaus Jacob [Freie Universität Berlin, Germany]; Rakhyun E. Kim [Utrecht University, Netherlands]; Peter King

[Institute for Global Environmental Strategies, Thailand]; Richard King [Chatham House, The Royal Institute of International Affairs, United Kingdom of Great Britain and Northern Ireland]; Andrei P. Kirilenko [University of Florida, United States of America]; Oswaldo Lucon [Sao Paulo State Environment Secretariat, Brazil]; Diana Mangalagiu [University of Oxford and Neoma Business School, United Kingdom of Great Britain and Northern Ireland]; Diego Martino [AAE Asesoramiento Ambiental Estratégico and ORT University, Uruguay]; Ritu Mathur [The Energy and Resources Institute (TERI), India]; Gavin Mudd [RMIT University, Australia]; Joni Seager [Bentley University, United States of America]; Sebastian Sewerin [Swiss Federal Institute of Technology Zurich (ETH Zurich), Switzerland]; Tim Stephens [University of Sydney, Australia]; Patricia Schwerdtle [Monash University, Australia]; Maria Jesus Iraola Trambauer (GEO Fellow) [University College London (UCL), United Kingdom of Great Britain and Northern Ireland]; Laura Wellesley [Chatham House, The Royal Institute of International Affairs, United Kingdom of Great Britain and Northern Ireland]; Caradee Y. Wright [Medical Research Council of South Africa, South Africa].

#### Chapter 18 Conclusions on Policy Effectiveness:

Klaus Jacob [Freie Universität Berlin, Germany]; Peter King [Institute for Global Environmental Strategies, Thailand]; Diana Mangalagiu [University of Oxford and Neoma Business School, United Kingdom of Great Britain and Northern Ireland]; Beatriz Rodríguez-Labajos (GEO Fellow) [Universitat Autònoma de Barcelona, Spain].

#### Chapter 19 Outlooks in GEO-6:

Ghassem R. Asrar [Pacific Northwest National Laboratory's (PNNL), United States of America]; Rohan Bhargava (GEO Fellow) [Utrecht University, Netherlands]; Paul Lucas [PBL Netherlands Environmental Assessment Agency, Netherlands]; Laura Pereira [Centre for Complex Systems in Transition (CST), Stellenbosch University, South Africa]; Detlef van Vuuren [PBL Netherlands Environmental Assessment Agency, Netherlands]; Joost Vervoort [Utrecht University, Netherlands].

#### Chapter 20 A long-term vision for 2050:

Mark Elder [Institute for Global Environmental Strategies, Japan]; Fintan Hurley [Institute of Occupational Medicine, United Kingdom of Great Britain and Northern Ireland]; Paul Lucas [PBL Netherlands Environmental Assessment Agency, Netherlands]; Maryam Meftahi (GEO Fellow) [Tehran Provincial Department of Environment, Iran (Islamic Republic of)]; Detlef van Vuuren [PBL Netherlands Environmental Assessment Agency, Netherlands].

#### Chapter 21 Future developments without targeted policies:

Katherine V. Calvin [Joint Global Change Research Institute, Pacific Northwest National Laboratory's (PNNL), United States of America]; Serena H. Chung [U.S. Environmental Protection Agency, United States of America]; Mike Harfoot [World Conservation Monitoring Centre (UNEP-WCMC), United Kingdom of Great Britain and Northern Ireland]; Steve Hedden [Frederick S. Pardee Center for International Futures, University of Denver, United States of America]; Barry B. Hughes

[Frederick S. Pardee Center for International Futures, University of Denver, United States of America]; Fintan Hurley [Institute of Occupational Medicine, United Kingdom of Great Britain and Northern Ireland]; Alexandre C. Köberle [Universidade Federal do Rio de Janeiro, Brazil]; Paul Lucas [PBL Netherlands Environmental Assessment Agency, Netherlands]; Katrina Lyne (GEO Fellow) [James Cook University, Australia]; Jonathan D. Moyer [Frederick S. Pardee Center for International Futures, University of Denver, United States of America]; Detlef van Vuuren [PBL Netherlands Environmental Assessment Agency, Netherlands]; Yoshihide Wada [International Institute for Applied Systems Analysis (IIASA), Austria].

#### Chapter 22 Pathways Toward Sustainable Development:

Lex Bouwman [PBL Netherlands Environmental Assessment Agency, Netherlands]; Katherine V. Calvin [Joint Global Change Research Institute, Pacific Northwest National Laboratory's (PNNL), United States of America]; Serena H. Chung [U.S. Environmental Protection Agency, United States of America]; Mike Harfoot [World Conservation Monitoring Centre (UNEP-WCMC), United Kingdom of Great Britain and Northern Ireland]; Chenmin He (GEO Fellow) [Peking University, China]; Steve Hedden [Frederick S. Pardee Center for International Futures, University of Denver, United States of America]; Barry B. Hughes [Frederick S. Pardee Center for International Futures, University of Denver, United States of America]; Fintan Hurley [Institute of Occupational Medicine, United Kingdom of Great Britain and Northern Ireland]; Alexandre C. Köberle [Universidade Federal do Rio de Janeiro, Brazil]; Paul Lucas [PBL Netherlands Environmental Assessment Agency, Netherlands]; Jonathan D. Moyer [Frederick S. Pardee Center for International Futures, University of Denver, United States of America]; Marco Rieckmann [University of Vechta, Germany]; Beatriz Rodríguez-Labajos (GEO Fellow) [Universitat Autònoma de Barcelona, Spain]; Detlef van Vuuren [PBL Netherlands Environmental Assessment Agency, Netherlands]; Yoshihide Wada [International Institute for Applied Systems Analysis (IIASA), Austria].

#### Chapter 23 Bottom-up Initiatives and Participatory Approaches for Outlooks:

Ghassem R. Asrar [Pacific Northwest National Laboratory's (PNNL), United States of America]; Rohan Bhargava (GEO Fellow) [Utrecht University, Netherlands]; Laur Hesse Fisher [Massachusetts Institute of Technology (MIT), United States of America]; Angel Hsu [Yale University, United States of America]; Thomas Malone [Massachusetts Institute of Technology (MIT), United States of America]; Jeanne Nel [Vrije Universiteit Amsterdam, Netherlands]; Laura Pereira [Centre for Complex Systems in Transition (CST), Stellenbosch University, South Africa]; Odirilwe Selomane [Stockholm Resilience Centre, Stockholm University, Sweden]; Nadia Sitas [Council for Scientific and Industrial Research (CSIR), South Africa]; Christopher Trisos [National Socio-Environmental Synthesis Center (SESYNC), University of Maryland, United States of America]; Mandy Angèl van den Ende (GEO Fellow) [Utrecht University, Netherlands]; Joost Vervoort [Utrecht University, Netherlands]; James Ward [University of South Australia, Australia]; Amy Weinfurter (GEO Fellow) [Data-Driven Yale, United States of America]; Yihao Xie [Yale-NUS College, Singapore]; Yaolin Zhang [Yale-NUS College, Singapore].

#### Chapter 24 The Way Forward:

Ghassem R. Asrar [Pacific Northwest National Laboratory's (PNNL), United States of America]; Kei Gomi [National Institute for Environmental Studies, Japan]; Steve Hedden [Frederick S. Pardee Center for International Futures, University of Denver, United States of America]; Fintan Hurley [Institute of Occupational Medicine, United Kingdom of Great Britain and Northern Ireland]; Klaus Jacob [Freie Universität Berlin, Germany]; Mikiko Kainuma [Institute for Global Environmental Strategies, Japan]; Peter King [Institute for Global Environmental Strategies, Thailand]; Diana Mangalagu [University of Oxford and Neoma Business School, United Kingdom of Great Britain and Northern Ireland]; Paul Lucas [PBL Netherlands Environmental Assessment Agency, Netherlands]; Robyn M. Lucas [National Centre for Epidemiology and Population Health, The Australian National University, Australia]; Laura Pereira [Centre for Complex Systems in Transition (CST), Stellenbosch University, South Africa]; Alexis Rocamora [Institute for Global Environmental Strategies (IGES), Japan]; Mandy Angèl van den Ende (GEO Fellow) [Utrecht University, Netherlands]; Detlef van Vuuren [PBL Netherlands Environmental Assessment Agency, Netherlands].

#### Chapter 25 Future Data and Knowledge Needs:

Graeme Clark [University of New South Wales, Australia]; Daniel Cooper [University of Oxford, United Kingdom of Great Britain and Northern Ireland]; Florence Mayocyc-Daguitan [Tebtebba (Indigenous Peoples' International Centre for Policy Research and Education), Philippines]; James Donovan [ADEC Innovations, United Kingdom of Great Britain and Northern Ireland]; Pali Lehohla [Pan African Institute for Evidence, South Africa]; Sheryl Joy Anne S. Gutierrez [ADEC Innovations, Philippines]; Nina Kruglikova [University of Oxford, United Kingdom of Great Britain and Northern Ireland]; Charles Mwangi [GLOBE Program, Kenya]; Amit R. Patel (GEO Fellow) [Planned Systems International Inc., United States of America]; Joni Seager [Bentley University, United States of America]; William Sonntag [The Group on Earth Observation Secretariat, United States of America]; Michelle Tan [ADEC Innovations, Kenya].

#### Fellows:

AlAnoud Alkhatlan [Arabian Gulf University, Bahrain]; Rohan Bhargava [Utrecht University, Netherlands]; Kari De Pryck [Sciences Po Paris, France]; Priyanka DeSouza [Massachusetts Institute of Technology, United States of America]; Souhir Hammami [Freie Universität Berlin, Germany]; Chenmin He [Peking University, China]; Matthew D. Kosko [University of Utah, United States of America]; Katrina Lyne [James Cook University, Australia]; Maryam Meftahi [Tehran Provincial Department of Environment, Iran (Islamic Republic of)]; Semie Memuna [Centre for International Governance Innovation, Canada]; Emma Gaalaas Mullaney [Bucknell University, United States of America]; Jaee Sanjay Nikam [Arizona State University, United States of America]; Amit R. Patel [Planned Systems International, Inc., United States of America]; Darshini Ravindranath [University College London (UCL), United Kingdom of Great Britain and Northern Ireland]; Beatriz Rodríguez-Labajos [Universitat Autònoma de Barcelona, Spain]; Mayar Sabet [CEDARE, Egypt]; Joeri Scholtens [University of

Amsterdam, Netherlands]; Patricia Nayna Schwerdtle [Monash University, Australia]; Maria Jesus Iraola Trambauer [University College London (UCL), United Kingdom of Great Britain and Northern Ireland]; Natalie Unterstell [Brazil]; Mandy Angèl van den Ende [Utrecht University, Netherlands]; Hung Vo [Harvard Graduate School of Design, United States of America]; Ying (Grace) Wang [Tongji University, China]; Amy Weinfurter [Data-Driven Yale, United States of America]; ChangXia Wu [Dalhousie University, Canada]; Leila Zamani [Department of Environment, Iran (Islamic Republic of)]; Carol Zastavniouk [Golder Associates, Canada].

#### High-Level Intergovernmental and Stakeholder Advisory Group:

Nassir S. Al-Amri, [King Abdulaziz University, Saudi Arabia]; Hæge Andenæs [Ministry of Climate and Environment, Norway]; Juan Carlos Arredondo [Secretariat de Medio Ambiente y Recursos Naturales, Mexico]; Julio Baena (alternate) [Ministry of the Environment, Brazil]; Sara Baisai Feresu [University of Zimbabwe, Zimbabwe]; Benon Bibbu Yassin [Ministry of Natural Resources, Energy and Environment, Malawi]; Simon Birkett [Clean Air in London, United Kingdom of Great Britain and Northern Ireland]; Gillian Bowser [Colorado State University, United States of America]; Joji Carino [Forest Peoples Programme, England]; Fernando E.L.S. Coimbra [Embassy of the Federative Republic of Brazil, Brazil]; Pascale Collas [Environment and Climate Change, Canada]; Marine Collignon (alternate) [Ministry of Foreign Affairs and International Development, France]; Victoria de Higa Rodriguez [Ministry of the Environment and Sustainable Development, Argentina]; Laksmi Dhewanthi [Ministry of Environment and Forestry, Indonesia]; Noasilalaonomenjahary Ambinintsoa Lucie [Ministry of Environment Ecology and Forest, Madagascar]; Arturo Flores Martinez (alternate) [Ministry of Environment and Natural Resources, Mexico]; Sascha Gabizon [WECF International, Germany]; Prudence Galega [Ministry of Environment, Protection of Nature and Sustainable Development, Cameroon]; Edgar Gutiérrez Espeleta [University of Costa Rica, Costa Rica]; Keri Holland (alternate) [U.S. Department of State, United States of America]; Pascal Valentin Houénou (vice-chair) [Université Nangui Abrogoua, Côte d'Ivoire]; Yi Huang (co-chair) [Peking University, China]; Mork-Knutsen Ingeborg (alternate) [Ministry of Climate and Environment, Norway]; Melinda Kimble [United Nations Foundation, United States of America]; Asdaporn Krairapanond [Office of Natural Resources and Environmental Policy and Planning, Thailand]; Yaseen M. Khayyat [Minister of Environment, Jordan]; Pierluigi Manzione [Ministry of Environment Land and Sea, Italy]; Veronica Marques (alternate) [Ministry of the Environment, Brazil]; Jock Martin [European Environment Agency, Denmark]; John M. Matuszak [U.S. Department of State, United States of America]; Megan Meaney [ICLEI – Local Governments for Sustainability, Canada]; Naser Moghaddasi [Department of Environment, Iran (Islamic Republic of)]; Bedrich Moldan [Charles University, Czech Republic]; Roger Roberge [Environment and Climate Change, Canada]; Najib Saab [General Authority for Meteorology and for Meteorology and Environment Protection, Saudi Arabia]; Mohammed Salahuddin [Ministry of Environment, Forests and Climate Change, India]; Jurgis Sapijanskas (alternate) [Ministry for the Ecological and Inclusive Transition of France, France]; Paolo Soprano (co-chair) [The Ministry for Environment, Land and Sea Protection of Italy, Italy]; Xavier Sticker [Ministry for

the Environment, France]; Sibylle Vermont (vice-chair) [Swiss Federal Office for the Environment, Switzerland]; Andrea Vincent (alternate) [University of Costa Rica, Costa Rica]; Terry Yosie [World Environment Center, United States of America].

#### Scientific Advisory Panel:

Asma Abahussain [Arabian Gulf University, Bahrain]; John B.R. Agard [The University of the West Indies, Jamaica]; Odeh Al-Jayyousi [Arabian Gulf University, Bahrain]; Paulo Eduardo Artaxo Netto [University of São Paulo, Brazil]; Rosina M. Bierbaum [University of Michigan, United States of America]; Enrico Giovannini [Università di Roma "Tor Vergata", Italy]; Sarah Green (co-chair) [Michigan Technological University, United States of America]; Torkil Jønh Clausen [World Water Council, France]; Ahmed Khater [National Water Research Center, Egypt]; Nicholas King (co-chair) [Independent, South Africa]; Paolo Laj [Institut des Géosciences de l'Environnement, France]; Byung-Kook Lee [Korea Environment Institute, Republic of Korea]; Alastair Charles Lewis [University of York, United Kingdom of Great Britain and Northern Ireland]; Franklyn Lisk [University of Warwick and HEART, United Kingdom of Great Britain and Northern Ireland]; Majid Shafiepour Motlagh [University of Tehran, Iran (Islamic Republic of)]; Carlos Afonso Nobre [National Institute of S&T for Climate Change, Brazil]; Toral Patel-Weyand [US Forest Service, United States of America]; Anand Patwardhan [University of Maryland School of Public Policy, United States of America]; N.H. Ravindranath [Indian Institute of Science, India]; Wendelin Stark [ETH Zurich, Switzerland]; Danling Tang [Chinese Academy of Sciences, China]; Maria del Mar Viana Rodriguez (vice-chair) [Spanish National Research Council, Spain]; Naohiro Yoshida [Tokyo Institute of Technology, Japan].

#### Assessment Methodologies, Data and Information Working Group

Maria Andrzejewska [UNEP/GRID-Warsaw, Poland]; Ousséni Arouna [Université Nationale des Sciences, Technologies, Ingénierie et Mathématiques, Bénin]; Sandra De Carlo (co-chair) [Presidency (Brazil)]; Rosario Gomez, Universidad del Pacifico, Peru]; Wabi Marcos [Ministère de l'Environnement Chargé de la Gestion des Changements Climatiques, Bénin]; Reza Maknoon [Amirkabir University of Technology, Iran (Islamic Republic of)]; Graciela Metternicht [University of New South Wales, Australia]; Thy Nguyen Van [Vietnam Environment Administration, Viet Nam]; Nicolas Perritaz (co-chair) [Federal Office for the Environment FOEN, Switzerland]; Qurat ul Ain Ahmad [Global Change Impact Studies Center, Pakistan]; Mathis Wackernagel [Global Footprint Network, United States of America]; Fei Wang [Northwest A&F University, China].

#### UNEP Extended Team:

Misha Alberizzi; Neville Ash; Jennifer Bailey; Matthew Billot; Peter Bjornsen; Oli Brown; Alex Caldas; Kilian Christ; Thierry De Oliveira; Fanny Demassieux; Francesco Gaetani; Tessa Goverse; Alexander Juras; Thomas Koetz; Pushpam Kumar; Monika MacDevette; Tomas Marques; Jacqueline McGlade; Abdelmenam Mohamed; Pascal Peduzzi; Corli Pretorius; Rula Qalyoubi; Tatiana Terekhova; Frank Turyatunga; Dirk Wagener; Clarice Wilson; Jinhua Zhang; Laetitia Zobel; Jochem Zoetelief; Sheeren Zorba.

### **Abundance**

The number of individuals or related measure of quantity (such as biomass) in a population, community or spatial unit.

### **Abrupt change**

The change that takes place so rapidly and unexpectedly that human or natural systems have difficulty adapting to it.

### **Acidification**

Change in natural chemical balance caused by an increase in the concentration of acidic elements.

### **Acidity**

A measure of how acid a solution may be. A solution with a pH of less than 7.0 is considered acidic.

### **Adaptation**

Adjustment in natural or human systems to a new or changing environment, including anticipatory and reactive adaptation, private and public adaptation, and autonomous and planned adaptation.

### **Adaptive capacity**

The ability of a system to adjust to climate change (including climate variability and extremes) to moderate potential damages, to take advantage of opportunities, or to cope with the consequences.

### **Adaptive governance**

A governance approach that incorporates methods of adaptive management, adaptive policy making and transition management for addressing complex, uncertain and dynamic issues. Adaptive governance relies on polycentric institutional arrangements for decision making at multiple scales. Spanning the local and global levels, this form of governance provides for collaborative, flexible, learning-based approaches to ecosystem management.

### **Aeroponics**

A plant-cultivation technique in which the roots hang suspended in the air while nutrient solution is delivered to them in the form of a fine mist climate geoengineering

**Afforestation**

Establishment of forest plantations on land that is not classified as forest.

**Aflatoxin**

Aflatoxins are poisonous substances produced by certain kinds of fungi (moulds) that are found naturally all over the world; they can contaminate food crops and pose a serious health threat to humans and livestock. Aflatoxins also pose a significant economic burden, causing an estimated 25 per cent or more of the world's food crops to be destroyed annually.

**Agglomeration economies**

The benefits that come when firms and people locate near one another together in cities and industrial clusters. These benefits all ultimately come from transport costs savings: the only real difference between a nearby firm and one across the continent is that it is easier to connect with a neighbor.

**Agricultural Intensification**

Agricultural intensification can be technically defined as an increase in agricultural production per unit of inputs (which may be labour, land, time, fertilizer, seed, feed or cash). For practical purposes, intensification occurs when there is an increase in the total volume of agricultural production that results from a higher productivity of inputs, or agricultural production is maintained while certain inputs are decreased (such as by more effective delivery of smaller amounts of fertilizer, better targeting of plant or animal protection, and mixed or relay cropping on smaller fields). Intensification that takes the form of increased production is most critical when there is a need to expand the food supply, for example during periods of rapid population growth. Intensification that makes more efficient use of inputs may be more critical when environmental problems or social issues are involved. In either case, changes caused by intensification are to be understood conceptually in contrast to extensive adjustments, which involve increases or decreases in the amount of inputs used. Historically, the most common and effective extensive adjustment in agricultural production has been to increase or decrease the area of land planted.

**Agroecology**

An ecological approach to agriculture that views agricultural areas as ecosystems and is concerned with the ecological impact of agricultural practices.

**Agroecosystems**

Organisms and environment of an agricultural area considered as an ecosystem.

**Agrotechnology**

The application of technology in agriculture.

**Albedo**

The fraction of solar energy that is diffusely reflected from the Earth back into space. It shows how reflective earth's surface is.

**Alienation**

Unlawfully transferring records or losing custody of them to an unauthorized organization or person.

**Alien species (also non-native, non-indigenous, foreign, exotic)**

Species accidentally or deliberately introduced outside its normal distribution.

**Alkalinisation**

A process that lowers the amount of acid in a solution. In medicine, an alkali, such as sodium bicarbonate, may be given to patients to lower high levels of acid in the blood or urine that can be caused by certain medicines or conditions.

**All-cause mortality**

All of the deaths that occur in a population, regardless of the cause. It is measured in clinical trials and used as an indicator of the safety or hazard of an intervention.

**Anthropocene**

A term used by scientists to name a new geologic epoch (following the most recent Holocene) characterized by significant changes in the Earth's atmosphere, biosphere and hydrosphere due primarily to human activities.

**Antimicrobial resistance**

The ability of a microorganism (like bacteria, viruses, and some parasites) to stop an antimicrobial (such as antibiotics, antivirals and antimalarials) from working against it. As a result, standard treatments become ineffective, infections persist and may spread to others.

**Aquatic ecosystem**

Basic ecological unit composed of living and non-living elements interacting in water.

**Aquifer**

An aquifer is an underground layer of water-bearing rock. Water-bearing rocks are permeable, meaning they have openings that liquids and gases can pass through. Sedimentary rock such as sandstone, as well as sand and gravel, are examples of water-bearing rock. The top of the water level in an aquifer is called the water table.

**Arable land**

Land under temporary crops (double-cropped areas are counted only once), temporary meadows for mowing or pasture, land under market and kitchen gardens, and land temporarily fallow (less than five years). The abandoned land resulting from shifting cultivation is not included in this category.

**Asymptote**

A line that continually approaches a given curve but does not meet it at any finite distance.

**Benthic**

Of, relating to, or occurring at the bottom of a body of water.

**Billion**

10<sup>9</sup> (1 000 000 000).

**Bioaccumulation**

The increase in concentration of a chemical in organisms. Also used to describe the progressive increase in the amount of a chemical in an organism resulting from rates of absorption of a substance in excess of its metabolism and excretion.

**Biocapacity**

The capacity of ecosystems to produce useful biological materials and to absorb waste materials generated by humans, using current management schemes and extraction technologies. The biocapacity of an area is calculated by multiplying the actual physical area by the yield factor and the appropriate equivalence factor. Biocapacity is usually expressed in units of global hectares.

**Biochemical Oxygen Demand**

A measure of the organic pollution of water: the amount of oxygen, in mg per litre of water, absorbed by a sample kept at 20°C for five days.

**Biodiversity (a contraction of biological diversity)**

The variety of life on Earth, including diversity at the genetic level, among species and among ecosystems and habitats. It includes diversity in abundance, distribution and behavior, as well as interaction with socio-ecological systems. Biodiversity also incorporates human cultural diversity, which can both be affected by the same drivers as biodiversity, and itself have impacts on the diversity of genes, other species and ecosystems.

**Bioenergy**

Renewable energy produced by living organisms.

**Biofuel**

Fuel produced from dry organic matter or combustible oils from plants, such as alcohol from fermented sugar or maize, and oils derived from oil palm, rapeseed or soybeans.

**Biogas**

Gas, rich in methane, which is produced by the fermentation of animal dung, human sewage or crop residues in an airtight container.

**Biogeochemical cycles**

The flow of chemical elements and compounds between living organisms (biosphere) and the physical environment (atmosphere, hydrosphere, lithosphere).

**Biomass**

Organic material, above and below ground and in water, both living and dead, such as trees, crops, grasses, tree litter and roots.

**Biomagnification**

The build-up of certain substances in the bodies of organisms at higher trophic levels of food webs. Organisms at lower trophic levels accumulate small amounts. Organisms at the next higher level of the food chain eat many of these lower-level organisms and hence accumulate larger amounts. The tissue concentration increases at each trophic level in the food web when there is efficient uptake and slow elimination.

**Biome**

The largest unit of ecosystem classification that is convenient to recognize below the global level. Terrestrial biomes are typically based on dominant vegetation structure (such as forest or grassland). Ecosystems within a biome function in

a broadly similar way, although they may have very different species composition. For example, all forests share certain properties regarding nutrient cycling, disturbance and biomass that are different from the properties of grasslands.

**Biosphere**

The part of the Earth and its atmosphere in which living organisms exist or that is capable of supporting life.

**Black carbon**

Operationally defined aerosol based on measurement of light absorption and chemical reactivity and/or thermal stability. Black carbon is formed through the incomplete combustion of fossil fuels, biofuel and biomass, and is emitted as part of anthropogenic and naturally occurring soot. It consists of pure carbon in several linked forms. Black carbon warms the Earth by absorbing sunlight and re-emitting heat to the atmosphere and by reducing albedo (the ability to reflect sunlight) when deposited on snow and ice.

**Bleaching (of coral reefs)**

A phenomenon occurring when corals under stress expel their mutualistic microscopic algae, called zooxanthellae. This results in a severe decrease or even total loss of photosynthetic pigments. Since most reef-building corals have white calcium carbonate skeletons, these then show through the corals' tissue and the coral reef appears bleached.

**Blue water**

Fresh surface and groundwater, in other words, the water in freshwater lakes, rivers and aquifers. The blue water footprint is the volume of surface and groundwater consumed as a result of the production of a good or service. Blue water consumption refers to the volume of freshwater used and then evaporated or incorporated into a product. It also includes water abstracted from surface or groundwater in a catchment and returned to another catchment or the sea. It is the amount of water abstracted from groundwater or surface water that does not return to the catchment from which it was withdrawn.

**Bottom-up**

From the lowest level of a hierarchy or process to the top.

**By-catch**

The unwanted fish and other marine creatures caught during commercial fishing for a different species.

**Cadastre**

A register of property showing the extent, value, and ownership of land for taxation.

**Capacity development**

The process through which individuals, organizations and societies obtain, strengthen and maintain the capabilities to set and achieve their own development objectives over time.

**Cap and trade (system)**

A regulatory or management system that sets a target level for emissions or natural resource use, and, after distributing shares in that quota, lets trading in those permits determine their price.

### **Capital**

Resource that can be mobilized in the pursuit of an individual's goals. Thus, natural capital (natural resources such as land and water), physical capital (technology and artefacts), social capital (social relationships, networks and ties), financial capital (money in a bank, loans and credit), human capital (education and skills).

### **Carbon dioxide equivalent (CO<sub>2</sub>-equivalent or CO<sub>2</sub>e)**

The universal unit of measurement used to indicate the global warming potential of the different greenhouse gases. Carbon dioxide – a naturally occurring gas that is a byproduct of burning fossil fuels and biomass, land-use changes and other industrial processes – is the reference against which other greenhouse gases are measured.

### **Carbon fertilization**

The CO<sub>2</sub> fertilization effect begins with enhanced photosynthetic CO<sub>2</sub> fixation. Non-structural carbohydrates tend to accumulate in leaves and other plant organs as starch, soluble carbohydrates or polyfructosans, depending on species. In some cases, there may be feedback inhibition of photosynthesis associated with accumulation of non-structural carbohydrates. Increased carbohydrate accumulation, especially in leaves, may be evidence that crop plants grown under CO<sub>2</sub> enrichment may not be fully adapted to take complete advantage of elevated CO<sub>2</sub>. This may be because the CO<sub>2</sub>-enriched plants do not have an adequate sink (inadequate growth capacity), or lack capacity to load phloem and translocate soluble carbohydrates. Improvement of photoassimilate utilization should be one goal of designing cultivars for the future.

### **Carbon sequestration**

The process of increasing the carbon content of a reservoir other than the atmosphere.

### **Carbon stock**

The quantity of carbon contained in a "pool," meaning a reservoir or system which has the capacity to accumulate or release carbon.

### **Cataracts**

A cloudiness or opacity in the normally transparent crystalline lens of the eye. This cloudiness can cause a decrease in vision and may lead to eventual blindness.

### **Catchment (area)**

The area of land from which precipitation drains into a river, basin or reservoir. See also Drainage basin.

### **Chikungunya**

Chikungunya is a viral disease transmitted to humans by infected mosquitoes. It causes fever and severe joint pain. Other symptoms include muscle pain, headache, nausea, fatigue and rash.

### **Circular economy**

A circular economy is a systems approach to industrial processes and economic activity that enables resources used to maintain their highest value for as long as possible.

Key considerations in implementing a circular economy are reducing and rethinking research use, and the pursuit of longevity, renewability, reusability, reparability, replaceability, upgradability for resources and products that are used.

### **Citizen science**

The collection and analysis of data relating to the natural world by members of the general public, typically as part of a collaborative project with professional scientists.

### **Citizen scientist**

A member of the general public who collects and analyses data relating to the natural world, typically as part of a collaborative project with professional scientists.

### **Civil society**

The aggregate of non-governmental organizations and institutions representing the interests and will of citizens.

### **Clean Development Mechanism (CDM)**

The mechanism provided by Article 12 of the Kyoto Protocol, designed to assist developing countries achieve sustainable development by permitting industrialized countries to finance projects for reducing greenhouse gas emissions in developing countries and receive carbon credits for doing so.

### **Climate change**

The UN Framework Convention on Climate Change defines climate change as "a change of climate which is attributed directly or indirectly to human activity that alters the composition of the global atmosphere and which is in addition to natural climate variability observed over comparable time periods."

### **Climate proofing**

A shorthand term for identifying risks to a development project, or any other specified natural or human asset, as a consequence of climate variability and change, and ensuring that those risks are reduced to acceptable levels through long-lasting and environmentally sound, economically viable, and socially acceptable changes implemented at one or more of the following stages in the project cycle: planning, design, construction, operation and decommissioning.

### **Climate variability**

Variations in the mean state and other statistics (such as standard deviations and the occurrence of extremes) of the climate on all temporal and spatial scales beyond that of individual weather events. Variability may be due to natural internal processes in the climate system (internal variability), or to variations in natural or anthropogenic external forcing (external variability).

### **Chlorofluorocarbons (CFCs)**

A group of chemicals, consisting of chlorine, fluorine and carbon, highly volatile and of low toxicity, widely used in the past as refrigerants, solvents, propellants and foaming agents. Chlorofluorocarbons have both ozone depletion and global warming potential.

**Community-based monitoring and information systems (CBMIS)**

This term refers to initiatives by indigenous peoples and local community organisations to monitor their community's well-being and the state of their territories and natural resources, applying a mix of traditional knowledge and innovative tools and approaches.

**Cross-cutting issue**

An issue that cannot be adequately understood or explained without reference to the interactions of several of its dimensions that are usually defined separately.

**Crowdsourcing**

A problem-solving and production process that involves outsourcing tasks to a network of people, also known as the crowd. This process can occur both online and offline.

**Conjunctival melanoma**

A pigmented lesion of the ocular surface. It is an uncommon but potentially devastating tumor that may invade the local tissues of the eye, spread systemically through lymphatic drainage and hematogenous spread, and recur in spite of treatment.

**Conservation**

The protection, care, management and maintenance of ecosystems, habitats, wildlife species and populations, within or outside of their natural environments, in order to safeguard the natural conditions for their long-term permanence.

**Crop**

(The total amount collected of) a plant such as a grain, fruit or vegetable grown in large amounts.

**Cultural services**

In the context of ecosystems, the non-material benefits for people, including spiritual enrichment, cognitive development, recreation and aesthetic experience.

**Custodian agencies**

United Nations bodies (and in some cases, other international organizations) responsible for compiling and verifying country data and metadata, and for submitting the data, along with regional and global aggregates, to the United Nations Statistics Division (UNSD). Furthermore, custodian agencies are expected to take the lead in developing missing indicators.

**Cutaneous malignant melanoma**

The most common subtype of malignant melanoma, a malignant neoplasm that arises from melanocytes. Melanocytes predominantly occur in the basal layer of the epidermis but do occur elsewhere in the body. Primary cutaneous melanoma is by far the most common type of primary melanoma, although it may occur in other tissues, e.g. primary uveal malignant melanoma.

**Dataset**

A collection of data on a particular issue.

**DDT (dichlorodiphenyltrichloroethane)**

A synthetic organochlorine insecticide, one of the persistent organic pollutants listed for control under the Stockholm Convention on Persistent Organic Pollutants.

**Decarbonization**

Remove carbon or carbonaceous deposits from (an engine or other metal object).

**Deforestation**

Conversion of forested land to non-forest areas.

**Dengue**

An infectious diseases caused by any one of four related viruses transmitted by mosquitoes. The dengue virus is a leading cause of illness and death in the tropic and subtropics. As many as 400 million people are infected yearly.

**Desertification**

Land degradation in arid, semi-arid and dry sub-humid areas resulting from various factors, including climatic variations and human activities. It involves crossing thresholds beyond which the underpinning ecosystem cannot restore itself, but requires ever-greater external resources for recovery.

**Detoxification**

The process of removing toxic substances or qualities.

**Disability-adjusted life years (DALYS)**

The sum of years of potential life lost due to premature mortality and the years of productive life lost due to disability.

**Disaggregation**

To separate into component parts.

**Disaster risk management**

The application of disaster risk reduction policies and strategies, to prevent new disaster risks, reduce existing disaster risks, and manage residual risks, contributing to the strengthening of resilience and reduction of losses. Disaster risk management actions can be categorized into; prospective disaster risk management, corrective disaster risk management and compensatory disaster risk management (also referred to as residual risk management).

**Disaster risk reduction**

The conceptual framework of elements intended to minimize vulnerability to disasters throughout a society, to avoid (prevention) or limit (mitigation and preparedness) the adverse impacts of hazards, within the broad context of sustainable development.

**DPSIR Framework**

UNEP adopted the DPSIR causal framework approach for the GEO assessments. This represents a systems-analysis view in which the driving forces of social and economic development exert pressures on the environment, which change the state of the environment. The changing state of the environment leads to impacts on, for example, human well-being and ecosystem health, which then produces human responses to remedy these impacts, such as social controls, redirecting investments, and/or policies and political interventions to influence human activity. Finally, these responses influence the state of the environment, either directly or indirectly, through the driving forces or the pressures. Existing policies increasingly need to be assessed in terms of how they address the drivers and impacts of environmental challenges.

**Drainage basin**

(Also called watershed, river basin or catchment)  
Land area where precipitation runs off into streams, rivers, lakes and reservoirs. It is a land feature that can be identified by tracing a line along the highest elevations between different areas, often a ridge.

**Drip irrigation**

Sometimes called trickle irrigation and involves dripping water onto the soil at very low rates (2-20 litres/hour) from a system of small diameter plastic pipes fitted with outlets called emitters or drippers. Water is applied close to plants so that only part of the soil in which the roots grow is wetted (Figure 60), unlike surface and sprinkler irrigation, which involves wetting the whole soil profile. With drip irrigation water, applications are more frequent (usually every 1-3 days) than with other methods and this provides a very favourable high moisture level in the soil in which plants can flourish.

**Driver**

The overarching socio-economic forces that exert pressures on the state of the environment.

**Drylands**

Areas characterized by lack of water, which constrain two major, linked ecosystem services: primary production and nutrient cycling. Four dryland sub-types are widely recognized: dry sub-humid, semi-arid, arid and hyper-arid, showing an increasing level of aridity or moisture deficit.

**E-waste (electronic waste)**

A generic term encompassing various forms of electrical and electronic equipment that has ceased to be considered of value and is disposed of.

**Early warning**

The provision of timely and effective information, through identified institutions, that allows individuals exposed to a hazard to take action to avoid or reduce their risk and prepare an effective response.

**Earth System**

The Earth System is a complex social-environmental system of interacting physical, chemical, biological and social components and processes that determine the state and evolution of the planet and life on it.

**Eco-design**

The integration of environmental aspects into product design and development with the aim of reducing adverse environmental impacts throughout a product's life cycle.

**Ecological footprint**

A measure of the area of biologically productive land and water an individual, population or activity uses to produce all the resources it consumes and to absorb the corresponding waste (such as carbon dioxide emissions from fossil fuel use), using prevailing technology and resource management practices. The ecological footprint is usually measured in global hectares.

**Ecoregion**

A major ecosystem defined by distinctive geography and receiving uniform solar radiation and moisture.

**Ecosystem**

A dynamic complex of plant, animal and micro-organism communities and their non-living environment, interacting as a functional unit.

**Ecosystem approach**

A strategy for the integrated management of land, water and living resources that promotes conservation and sustainable use in an equitable way. An ecosystem approach is based on the application of appropriate scientific methods, focused on levels of biological organization that encompass the essential structure, processes, functions and interactions among and between organisms and their environment. It recognizes that humans, with their cultural diversity, are an integral component of many ecosystems.

**Ecosystem boundaries**

Ecosystem boundaries are zones of transitions between two adjacent habitats. They occur naturally in all biomes but the extent of boundaries has been greatly increased by anthropogenic habitat modification. Transition zones are characterized by a profound change in the composition of plant and animal communities and that transition may be abrupt, gradual or even occur via a series of intermediate habitat types.

**Ecosystem collapse**

The endpoint of ecosystem decline, and occurs when all occurrences of an ecosystem have moved outside the natural range of spatial and temporal variability in composition, structure and/or function.

**Ecosystem function**

An intrinsic ecosystem characteristic related to the set of conditions and processes whereby an ecosystem maintains its integrity (such as primary productivity, food chain and biogeochemical cycles). Ecosystem functions include such processes as decomposition, production, nutrient cycling, and movements of nutrients and energy.

**Ecosystem health**

The degree to which ecological factors and their interactions are reasonably complete and function for continued resilience, productivity and renewal of the ecosystem.

**Ecosystem management**

An approach to maintaining or restoring the composition, structure, function and delivery of services of natural and modified ecosystems for the goal of achieving sustainability. It is based on an adaptive, collaboratively developed vision of desired future conditions that integrates ecological, socio-economic, and institutional perspectives, applied within a geographic framework, and defined primarily by natural ecological boundaries.

**Ecosystem resilience**

The level of disturbance that an ecosystem can withstand without crossing a threshold to become a different structure or deliver different outputs. Resilience depends on ecological dynamics as well as human organizational and institutional capacity to understand, manage and respond to these dynamics.

**Ecosystem restoration**

The process of assisting the recovery of an ecosystem that has been degraded, damaged or destroyed.

**Ecosystem-based adaptation**

The use of biodiversity and ecosystem services as part of an overall strategy to help people adapt to the adverse effects of climate change.

**Ecotourism**

Travel undertaken to witness the natural or ecological quality of particular sites or regions, including the provision of eco-friendly services to facilitate such travel.

**Effluent**

In issues of water quality, refers to liquid waste (treated or untreated) discharged to the environment from sources such as industrial process and sewage treatment plants.

**El Niño (also El Niño-Southern Oscillation (ENSO))**

In its original sense, it is a warm water current that periodically flows along the coast of Ecuador and Peru, disrupting the local fishery. This oceanic event is associated with a fluctuation of the inter-tropical surface pressure pattern and circulation in the Indian and Pacific Oceans, called the Southern Oscillation. This atmosphere-ocean phenomenon is collectively known as El Niño-Southern Oscillation. During an El Niño event, the prevailing trade winds weaken and the equatorial countercurrent strengthens, causing warm surface waters in the Indonesian area to flow eastward to overlie the cold waters of the Peru current off South America. This event has great impact on the wind, sea surface temperature and precipitation patterns in the tropical Pacific. It has climatic effects throughout the Pacific region and in many other parts of the world. The opposite of an El Niño event is called La Niña.

**Electrification**

The action or process of charging something with electricity.

**Emission inventory**

Details the amounts and types of pollutants released into the environment.

**Endangered species**

A species is endangered when the best available evidence indicates that it meets any of the criteria A to E specified for the endangered category of the IUCN Red List, and is therefore considered to be facing a very high risk of extinction in the wild.

**Endocrine disruptor**

An external substance that interferes (through mimicking, blocking, inhibiting or stimulating) with function(s) of the hormonal system and consequently causes adverse health effects in an intact organism, or its progeny, or (sub) populations.

**Energy intensity**

Ratio of energy consumption to economic or physical output. At the national level, energy intensity is the ratio of total domestic primary energy consumption or final energy

consumption to gross domestic product or physical output. Lower energy intensity shows greater efficiency in energy use.

**Environment statistics**

Statistics that describe the state of and trends in the environment, covering the media of the natural environment (air/ climate, water, land/soil), the living organisms within the media, and human settlements.

**Environmental assessment**

The entire process of undertaking an objective evaluation and analysis of information designed to support environmental decision making. It applies the judgement of experts to existing knowledge to provide scientifically credible answers to policy-relevant questions, quantifying where possible the level of confidence. It reduces complexity but adds value by summarizing, synthesizing and building scenarios, and identifies consensus by sorting out what is known and widely accepted from what is not known or not agreed. It sensitizes the scientific community to policy needs and the policy community to the scientific basis for action.

**Environmental degradation**

Environmental degradation is the deterioration in environmental quality from ambient concentrations of pollutants and other activities and processes such as improper land use and natural disasters.

**Environmental education**

The process of recognizing values and clarifying concepts in order to develop skills and attitudes necessary to understand and appreciate the interrelatedness of humans, their culture and biophysical surroundings. Environmental education also entails practice in decision-making and self-formulation of a code of behaviour about issues concerning environmental quality.

**Environmental flows**

Quantity, timing and quality of water flows required to sustain freshwater and estuarine ecosystems and the human livelihoods and well-being that depend on these ecosystems. Through implementation of environmental flows, water managers strive to achieve a flow regime, or pattern, that provides for human uses and maintains the essential processes required to support healthy river ecosystems.

**Environmental footprint**

The effect that a person, company, activity, etc. has on the environment, for example the amount of natural resources that they use and the amount of harmful gases that they produce.

**Environmental governance**

Environmental Governance is the means by which society determines and acts on goals and priorities related to the management of natural resources. This includes the rules, both formal and informal, that govern human behavior in decision-making processes as well as the decisions themselves. Appropriate legal frameworks on the global, regional, national and local level are a prerequisite for good environmental governance.

### **Environmental health**

Those aspects of human health and disease that are determined by factors in the environment. It also refers to the theory and practice of assessing and controlling factors in the environment that can potentially affect health. Environmental health includes both the direct pathological effects of chemicals, radiation and some biological agents, and the effects, often indirect, on health and well-being of the broad physical, psychological, social and aesthetic environment. This includes housing, urban development, land use and transport.

### **Environmental impact assessment (EIA)**

An analytical process or procedure that systematically examines the possible environmental consequences of a given activity or project. The aim is to ensure that the environmental implications are taken into account before the decisions are made.

### **Environmental justice**

A mechanism of accountability for the protection of rights and the prevention and punishment of wrongs related to the disproportionate impacts of growth on the poor and vulnerable in society from rising pollution and degradation of ecosystem services, and from inequitable access to and benefits from the use of natural assets and extractive resources.

### **Environmental monitoring**

Regular, comparable measurements or time series of data on the environment.

### **Environmental policy**

A policy aimed at addressing environmental problems and challenges.

### **Environmental pressure**

Pressure resulting from human activities which bring about changes in the state of the environment.

### **Environmental refugees and internally displaced people (IDPs)**

People who have been forced to leave their traditional habitat temporarily or permanently, because of a marked environmental disruption (natural or triggered by people) that jeopardizes their existence and/or seriously affected the quality of their life. (Science for Peace) belong to a larger group of immigrants known as environmental refugees. Environmental refugees include immigrants forced to flee because of natural disasters, such as volcanoes and tsunamis.

### **Epidemiology**

The branch of medicine which deals with the incidence, distribution, and possible control of diseases and other factors relating to health.

### **Equity**

Fairness of rights, distribution and access. Depending on context, this can refer to access to resources, services or power.

### **Estuary**

Water passage where the tide meets a river current.

### **Eutrophication**

The degradation of water or land quality due to enrichment by nutrients, primarily nitrogen and phosphorous, which results in excessive plant (principally algae) growth and decay. Eutrophication of a lake normally contributes to its slow evolution into a bog or marsh and ultimately to dry land. Eutrophication may be accelerated by human activities that speed up the ageing process.

### **Evapotranspiration**

Combined loss of water by evaporation from the soil or surface water, and transpiration from plants and animals.

### **External cost (also externality)**

A cost that is not included in the market price of the goods and services produced. In other words, a cost not borne by those who create it, such as the cost of cleaning up contamination caused by discharge of pollution into the environment.

### **Feed-in tariff**

A feed-in tariff is an energy policy focused on supporting the development and dissemination of renewable power generation. In a feed-in tariff scheme, providers of energy from renewable sources, such as solar, wind or water, receive a price for what they produce based on the generation costs. This purchase guarantee is offered generally on a long-term basis, ranging from 5 to 20 years, but most commonly spanning 15–20 years.<sup>1</sup> The cost of the tariff payments are typically shared with the electricity consumers.

### **Feedback**

Where non-linear change is driven by reactions that either dampen change (negative feedbacks) or reinforce change (positive feedbacks).

### **Fipronil systemic insecticides**

Phenyl-pyrazole fipronil are insecticides with systemic properties. Their physicochemical characteristics, mainly assessed in terms of their octanol water partition coefficient (*K<sub>ow</sub>*) and dissociation constant (*pK<sub>a</sub>*), enable their entrance into plant tissues and their translocation to all its parts. Regardless of the manner of application and route of entry to the plant, they translocate throughout all plant tissues making them toxic to any insects (and potentially other organisms) that feed upon the plant. This protects the plant from direct damage by herbivorous (mainly sap feeding) insects and indirectly from damage by plant viruses that are transmitted by insects.

### **Floods (river, flash and storm surge)**

Usually classified into three types: river flood, flash flood and storm surge. River floods result from intense and/or persistent rain over large areas. Flash floods are mostly local events resulting from intense rainfall over a small area in a short period of time. Storm surge floods occur when flood water from the ocean or large lakes is pushed on to land by winds or storms.

### **Food security**

Physical and economic access to food that meets people's dietary needs as well as their food preferences.

### **Food system**

1) Food systems are usually conceived as a set of activities ranging from production to consumption. It is a broad concept encompassing food security and its components – availability, access and utilization – and including the social and environmental outcomes of these activities. Food systems in developing countries have been largely transformed by globalization. This change offers tremendous opportunities for food workers to access new and better employments. Yet, small scale food producers and other food workers are still too often excluded from the benefits generated by food businesses.

### **Food-water-energy nexus**

The water-food-energy nexus is central to sustainable development. Demand for all three is increasing, driven by a rising global population, rapid urbanization, changing diets and economic growth. Agriculture is the largest consumer of the world's freshwater resources, and more than one-quarter of the energy used globally is expended on food production and supply. The inextricable linkages between these critical domains require a suitably integrated approach to ensuring water and food security, and sustainable agriculture and energy production worldwide.

### **Forest**

Land spanning more than 0.5 hectares with trees higher than 5 metres and a canopy cover of more than 10 per cent, or trees able to reach these thresholds *in situ*. It does not include land that is predominantly under agricultural or urban use.

### **Forest degradation**

Changes within the forest that negatively affect the structure or function of the stand or site, and thereby lower the capacity to supply products and/or services.

### **Forest management**

The processes of planning and implementing practices for the stewardship and use of forests and other wooded land aimed at achieving specific environmental, economic, social and/or cultural objectives.

### **Forest plantation**

Forest stands established by planting and/or seeding in the process of afforestation or reforestation. They are either of introduced species (all planted stands), or intensively managed stands of indigenous species, which meet all the following criteria: contain one or two species, are of similar age and regularly spaced. "Planted forest" is another term used for plantation.

### **Fossil fuel**

Coal, natural gas and petroleum products (such as oil) formed from the decayed bodies of animals and plants that died millions of years ago.

### **Free-riding**

Free riding occurs when one firm (or individual) benefits from the actions and efforts of another without paying or sharing the costs. For example, a retail store may initially choose to incur costs of training its staff to demonstrate to potential

customers how a particular kitchen appliance works. It may do so in order to expand its sales. However, the customers may later choose to buy the product from another retailer selling at a lower price because its business strategy is not to incur these training and demonstration costs. This second retailer is viewed as "free riding" on the efforts and the costs incurred by the first retailer. If such a situation persists, the first retailer will not have the incentive to continue.

### **Gender**

Gender refers to the roles, behaviors, activities, and attributes that a given society at a given time considers appropriate for men and women. In addition to the social attributes and opportunities associated with being male and female and the relationships between women and men and girls and boys, gender also refers to the relations between women and those between men. These attributes, opportunities and relationships are socially constructed and are learned through socialization processes. They are context/ time-specific and changeable. Gender determines what is expected, allowed and valued in a woman or a man in a given context. Gender is part of the broader socio-cultural context, as are other important criteria for socio-cultural analysis including class, race, poverty level, ethnic group, sexual orientation, age, etc.

### **Gender analysis**

Gender analysis is a critical examination of how differences in gender roles, activities, needs, opportunities and rights/ entitlements affect men, women, girls and boys in certain situation or contexts. Gender analysis examines the relationships between females and males and their access to and control of resources and the constraints they face relative to each other. A gender analysis should be integrated into all sector assessments or situational analyses to ensure that gender-based injustices and inequalities are not exacerbated by interventions, and that where possible, greater equality and justice in gender relations are promoted.

### **Gender equality (Equality between women and men)**

This refers to the equal rights, responsibilities and opportunities of women and men and girls and boys. Equality does not mean that women and men will become the same but that women's and men's rights, responsibilities and opportunities will not depend on whether they are born male or female. Gender equality implies that the interests, needs and priorities of both women and men are taken into consideration, recognizing the diversity of different groups of women and men. Gender equality is not a women's issue but should concern and fully engage men as well as women. Equality between women and men is seen both as a human rights issue and as a precondition for, and indicator of, sustainable people-centered development.

### **Gender gap**

The term gender gap refers to any disparity between women and men's condition or position in society. It is often used to refer to a difference in average earnings between women and men, e.g. "gender pay gap." However, gender gaps can be found in many areas, such as economic participation and opportunity, educational attainment, health and survival and political empowerment.

**Gender mainstreaming**

Gender mainstreaming is the chosen strategy of the United Nations system for implementing greater equality for women and girls in relation to men and boys. Mainstreaming a gender perspective is the process of assessing the implications for women and men of any planned action, including legislation, policies or programs, in all areas and at all levels. It is a way to make women's as well as men's concerns and experiences an integral dimension of the design, implementation, monitoring and evaluation of policies and programs in all political, economic and societal spheres so that women and men benefit equally and inequality is not perpetuated. The ultimate goal is to achieve gender equality.

**Gender-disaggregated data**

Information collected and presented separately according to people's gender. It typically includes the state of being masculine or feminine based on social or cultural identities, constructs and differences.

**Genetic diversity**

The variety of genes within a particular species, variety or breed.

**GEO Data Portal (now Environmental Data Explorer)**

The source for datasets used by UNEP and its partners in the Global Environment Outlook report and other integrated environmental assessments. Its online database holds more than 500 different variables, including national, sub-regional, regional and global statistics as well as geospatial datasets (maps), covering themes such as freshwater, population, forests, emissions, climate, disasters, health and GDP.

**Geomorphology**

The study of the physical features of the surface of the earth and their relation to its geological structures.

**Geospatial**

Relating to or denoting data that is associated with a particular location.

**Geostationary orbit**

Circular orbit 35,785 km (22,236 miles) above Earth's Equator in which a satellite's orbital period is equal to Earth's rotation period of 23 hours and 56 minutes. A spacecraft in this orbit appears to an observer on Earth to be stationary in the sky. This particular orbit is used for meteorological and communications satellites. The geostationary orbit is a special case of the geosynchronous orbit, which is any orbit with a period equal to Earth's rotation period.

**Geothermal energy**

The word geothermal comes from the Greek words geo (earth) and therme (heat). Geothermal energy is heat within the earth. People can use this heat as steam or as hot water to heat buildings or to generate electricity. Geothermal energy is a renewable energy source because heat is continuously produced inside the earth.

**Glacial periods**

A period in the earth's history when polar and mountain ice sheets were unusually extensive across the earth's surface.

**Glacier retreat**

Glaciers retreat when their terminus does not extend as far downvalley as it previously did. Glaciers may retreat when their ice melts or ablates more quickly than snowfall can accumulate and form new glacial ice. Higher temperatures and less snowfall have been causing many glaciers around the world to retreat recently.

**Global (international) environmental governance**

The assemblage of laws and institutions that regulate society-nature interactions and shape environmental outcomes.

**Global commons**

Natural un-owned assets such as the atmosphere, oceans, outer space and the Antarctic.

**Global Earth Observation System of Systems (GEOSS)**

A network aiming to link existing and planned Earth observing systems (e.g., satellites and networks of weather stations and ocean buoys) around the world, support the development of new systems where gaps currently exist, and promote common technical standards so that data from the thousands of different instruments can be combined into coherent datasets. It aims to provide decision support tools to policy makers and other users in areas such as health, agriculture and disasters.

**Global hectare**

A hypothetical hectare with world-average ability to produce resources and absorb wastes.

**Global observation system**

A set of coordinated monitoring activities that would collect much needed data at a global scale on a variety of indicators such as biodiversity, water quality and quantity, atmospheric pollution, land degradation and chemical release.

**Global public good**

Public goods that have universal benefits, covering multiple groups of countries and all populations.

**Global warming**

Increase in surface air temperature, referred to as the global temperature, induced by emissions of greenhouse gases into the air.

**Globalization**

The increasing integration of economies and societies around the world, particularly through trade and financial flows, and the transfer of culture and technology.

**Governance**

The act, process, or power of governing for the organization of society/ies. For example, there is governance through the state, the market, or through civil society groups and local organizations. Governance is exercised through institutions: laws, property-rights systems and forms of social organization.

**Green economy**

There is no internationally agreed definition of green economy and at least eight separate definitions were identified in recent publications. For example, UNEP has defined the green economy as "one that results in improved human well-being and social equity, while significantly reducing environmental

risks and ecological scarcities. It is low carbon, resource efficient, and socially inclusive" (UNEP, 2011). This definition has been cited in a number of more recent reports, including by the UNEMG and the OECD. Another definition for green economy offered by the Green Economy Coalition (a group of NGOs, trade union groups and others doing grassroots work on a green economy) succinctly defines green economy as "a resilient economy that provides a better quality of life for all within the ecological limits of the planet."

#### **Greenhouse gases (GHGs)**

Gaseous constituents of the atmosphere, both natural and anthropogenic, that absorb and emit thermal radiation. This property causes the greenhouse effect. Water vapour (H<sub>2</sub>O), carbon dioxide (CO<sub>2</sub>), nitrous oxide (N<sub>2</sub>O), methane (CH<sub>4</sub>) and ozone (O<sub>3</sub>) are the primary greenhouse gases in the Earth's atmosphere. There are human-made greenhouse gases in the atmosphere, such as halocarbons and other chlorine- and bromine-containing substances. Beside CO<sub>2</sub>, N<sub>2</sub>O and CH<sub>4</sub>, the Kyoto Protocol deals with sulphur hexafluoride (SF<sub>6</sub>), hydrofluorocarbons (HFCs), perfluorocarbons (PFCs) and nitrogen trifluoride (NF<sub>3</sub>).

#### **Grey water**

Water the quality of which has been adversely affected by human use, in industrial, agriculture or domestically. The grey water footprint of a product is an indicator of freshwater pollution that can be associated with the production of a product over its full supply chain. It is defined as the volume of freshwater that is required to assimilate the load of pollutants based on natural background concentrations and existing ambient water quality standards. It is calculated as the volume of water that is required to dilute pollutants to such an extent that the quality of the water remains above agreed water quality standards.

#### **Gross domestic product (GDP)**

The value of all final goods and services produced in a country in one year. GDP can be measured by adding up all of an economy's incomes – wages, interest, profits, and rents – or expenditures – consumption, investment, government purchases, and net exports (exports minus imports).

#### **Ground truthing**

A process by which the content of satellite images, aerial photographs – or maps based on them – is compared with the reality on the ground through site visits and field surveys. It is used to verify the accuracy of the images or the way they have been interpreted to produce maps.

#### **Groundwater**

Water that flows or seeps downward and saturates soil or rock, supplying springs and wells. The upper surface of the saturated zone is called the water table.

#### **Gyres**

A large system of rotating ocean currents, primarily driven by wind movement. Large gyres exist in the Indian Ocean, North Atlantic, North Pacific, South Atlantic and South Pacific.

#### **Habitat fragmentation**

Alteration of habitat resulting in spatial separation of habitat units from a previous state of greater continuity.

#### **Habitat**

(1) The place or type of site where an organism or population occurs naturally.

(2) Terrestrial or aquatic areas distinguished by geographic, living and non-living features, whether entirely natural or semi-natural.

#### **Hadley cell**

A large-scale atmospheric convection cell in which air rises at the equator and sinks at medium latitudes, typically about 30° north or south.

#### **Hazard**

A potentially damaging physical event, phenomenon or human activity that may cause the loss of life or injury, property damage, social and economic disruption or environmental degradation.

#### **Hazardous waste**

A used or discarded material that can damage human health and the environment. Hazardous wastes may include heavy metals, toxic chemicals, medical wastes or radioactive material.

#### **Heavy metals**

A subset of elements that exhibit metallic properties, including transitional metals and semi-metals (metalloids), such as arsenic, cadmium, chromium, copper, lead, mercury, nickel and zinc, that have been associated with contamination and potential toxicity.

#### **Helminth**

Worm-like parasites.

#### **Heterogeneities**

The quality or state of being diverse in character or content.

#### **High seas**

The oceans outside national jurisdictions, lying beyond each nation's exclusive economic zone or other territorial waters.

#### **Human footprint**

The impact of human activities measured in terms of the area of biologically productive land and water required to produce the goods consumed and to assimilate the wastes generated.

#### **Human health**

Health is a state of complete physical, mental and social well-being and not merely the absence of disease or infirmity.

#### **Human well-being**

The extent to which individuals have the ability to live the kinds of lives they have reason to value; the opportunities people have to pursue their aspirations. Basic components of human well-being include: security, meeting material needs, health and social relations.

#### **Hybridization**

The process of an animal or plant breeding with an individual of another species or variety.

### **Hydraulic fracturing**

The gas-fired plants come courtesy of the revolution in hydraulic fracturing ("fracking"), which has delivered a vast supply of low-cost natural gas to an electricity market that has struggled with steadily rising coal prices since 2001.

### **Hydrochlorofluorocarbons (HCFCs)**

Organic and human-made substances composed of hydrogen, chlorine, fluorine and carbon atoms. As the ozone-depleting potential of HCFCs is much lower than that of CFCs, HCFCs were considered acceptable interim substitutes for CFCs.

### **Hydrological cycle**

Succession of stages undergone by water in its passage from the atmosphere to the Earth's surface and its return to the atmosphere. The stages include evaporation from land, sea or inland water, condensation to form clouds, precipitation, accumulation in the soil or in water bodies, and re-evaporation.

### **Hydrometeorology**

A branch of meteorology that deals with water in the atmosphere especially as precipitation.

### **Hydroponics**

The process of growing plants in sand, gravel, or liquid, with added nutrients but without soil.

### **Hypoxia**

Lack of oxygen. In the context of eutrophication and algal blooms, hypoxia is the result of a process that uses up dissolved oxygen in the water. Algal blooms cause water to become more opaque, thereby reducing light availability to submerged aquatic vegetation, and interfering with beneficial human water uses. When the bloom dies off, algae sink to the bottom and are decomposed by bacteria using up the available oxygen. Hypoxia is particularly severe in the late summer, and can be so severe in some areas that they are referred to as "dead zones" because only bacteria can survive there.

### **IAS Invasive alien species**

Invasive alien species are plants, animals, pathogens and other organisms that are non-native to an ecosystem, and which may cause economic or environmental harm or adversely affect human health. In particular, they impact adversely upon biodiversity, including decline or elimination of native species - through competition, predation, or transmission of pathogens - and the disruption of local ecosystems and ecosystem functions.

### **Improved drinking water**

"Improved" sources of drinking water include piped water into dwellings; piped water into yards/plots; public taps or standpipes; tube wells or boreholes; protected dug wells; protected springs; and rainwater.

### **Improved sanitation**

"Improved" sanitation includes flush lavatories; piped sewer systems; septic tanks; flush/pour flush to pit latrines; ventilated improved pit latrines (VIP); pit latrines with slab; composting lavatories.

### **In vitro**

(Of a process) performed or taking place in a test tube, culture dish, or elsewhere outside a living organism.

### **Inertial forces**

Any force invoked by an observer to maintain the validity of Isaac Newton's second law of motion in a reference frame that is rotating or otherwise accelerating at a constant rate. For specific inertial forces, see centrifugal force; Coriolis force; d'Alembert's principle.

### **Institutions**

Regularized patterns of interaction by which society organizes itself: the rules, practices and conventions that structure human interaction. The term is wide and encompassing, and could be taken to include law, social relationships, property rights and tenurial systems, norms, beliefs, customs and codes of conduct as much as multilateral environmental agreements, international conventions and financing mechanisms. Institutions could be formal (explicit, written, often having the sanction of the state) or informal (unwritten, implied, tacit, mutually agreed and accepted).

### **Integrated coastal zone management**

Approaches that integrate economic, social and ecological perspectives for the management of coastal resources and areas.

### **Integrated water resources management (IWRM)**

A process which promotes the coordinated development and management of water, land and related resources, in order to maximize the resultant economic and social welfare in an equitable manner without compromising the sustainability of vital ecosystems.

### **Intersectionality**

The understanding that social roles and identities overlap and have intertwined effects. The identity of any individual reflects and is shaped by a range of social and cultural categories such as race, class, gender, sexual orientation, and religion (among others). Oppressions within society are enacted through these multiple and linked identities.

### **Invasive species**

Introduced species that have spread beyond their area of introduction (and, rarely, native species that have recently expanded their populations), and which are frequently associated with negative impacts on the environment, human economy or human health.

### **Jetstream**

A narrow variable band of very strong predominantly westerly air currents encircling the globe several miles above the earth. There are typically two or three jet streams in each of the northern and southern hemispheres.

### **Keratinocyte**

Cells found in the epidermis. Keratinocytes at the outer surface of the epidermis are dead and form a tough protective layer. The cells underneath divide to replenish the supply.

### **Kyoto Protocol**

A protocol to the 1992 United Nations Framework Convention on Climate Change (UNFCCC) adopted at the Third Session of the Conference of the Parties to the UNFCCC in 1997 in Kyoto, Japan. It contains legally binding commitments in addition to those included in the UNFCCC. Countries included in Annex B of the protocol (most OECD countries and countries

with economies in transition) agreed to control their national anthropogenic emissions of greenhouse gases (CO<sub>2</sub>, CH<sub>4</sub>, N<sub>2</sub>O, HFCs, PFCs, SF<sub>6</sub> and NF<sub>3</sub>) so that the total emissions from these countries would be at least 5 per cent below 1990 levels in the commitment period, 2008 to 2012.

#### **Land cover**

The physical coverage of land, usually expressed in terms of vegetation cover or lack of it. Influenced by but not synonymous with land use.

#### **Land degradation neutrality**

A state whereby the amount and quality of land resources, necessary to support ecosystem functions and services and enhance food security, remains stable or increases within specified temporal and spatial scales and ecosystems.

#### **Land degradation neutrality**

A state whereby the amount and quality of land resources, necessary to support ecosystem functions and services and enhance food security, remains stable or increases within specified temporal and spatial scales and ecosystems.

#### **Land degradation**

A long-term loss of ecosystem function and services, caused by disturbances from which the system cannot recover unaided.

#### **Land grabbing**

Large-scale land grabbing is defined as “acquisitions or concessions that are one or more of the following: (i) in violation of human rights, particularly the equal rights of women; (ii) not based on free, prior and informed consent of affected land-users; (iii) not based on a thorough assessment, or in disregard of social, economic and environmental impacts including the way those impacts are gendered; (iv) not based on transparent contracts that specify clear and binding commitments about activities, employment and benefits sharing; and (v) not based on effective democratic planning, independent oversight and meaningful participation.”

#### **Land Tenure**

The relationship, whether legally or customarily defined, among people, as individuals or groups, with respect to land. (For convenience, “land” is used here to include other natural resources such as water and trees.) Land tenure is an institution, i.e., rules invented by societies to regulate behaviour. Rules of tenure define how property rights to land are to be allocated within societies. They define how access is granted to rights to use, control, and transfer land, as well as associated responsibilities and restraints. In simple terms, land tenure systems determine who can use what resources for how long, and under what conditions.

#### **Land use planning**

The systematic assessment of land and water potential, alternative patterns of land use and other physical, social and economic conditions, for the purpose of selecting and adopting land-use options which are most beneficial to land users.

#### **Land use**

The functional dimension of land for different human purposes or economic activities. Examples of land use categories include agriculture, industrial use, transport and protected areas.

#### **Land-use planning**

Land-use planning involves the systematic assessment of environmental, economic and social impacts of the range of potential uses of land in order to decide on the optimal pattern of land use. Land-use planning and systematic conservation planning has seldom been explored explicitly as a tool in global scenarios.

#### **Legitimacy**

Measure of political acceptability or perceived fairness. State law has its legitimacy in the state; local law and practices work on a system of social sanction, in that they derive their legitimacy from a system of social organization and relationships.

#### **Leverage point**

A place in a system's structure where a relatively small amount of force can effect change. It is a low leverage point if a small amount of force causes a small change in system behaviour, or a high leverage point if a small amount of force causes a large change.

#### **Life-cycle analysis**

A technique to assess the environmental impacts associated with all the stages of the life of a product – from raw material extraction through materials processing, manufacture, distribution, use, repair and maintenance, and disposal or recycling (cradle-to-grave).

#### **Lifetime (in the atmosphere)**

The approximate amount of time it takes for concentrations of an atmospheric pollutant to return to the background level (assuming emissions cease) as a result of either being converted to another chemical compound or being taken out of the atmosphere through a sink. Atmospheric lifetimes can vary from hours or weeks (sulphate aerosols) to more than a century (CFCs).

#### **Livelihood**

(The way someone earns) the money people need to pay for food, a place to live, clothing, etc.

#### **Mainstreaming**

Taking into consideration as an integral part of the issue in question.

#### **Mangrove**

A tree or shrub that grows in chiefly tropical coastal swamps that are flooded at high tide. Mangroves typically have numerous tangled roots above ground and form dense thickets.

#### **Marginalization**

Treatment of a person, group, or concept as insignificant or peripheral.

#### **Mariculture**

The cultivation of marine organisms in their natural environment.

#### **Marine protected area (MPA)**

A geographically defined marine area that is designated or regulated and managed to achieve specific conservation objectives.

### **Market-based instrument**

Market-based instruments span a range of measures and approaches. Fundamentally, they are policy measures that influence outcomes through their effect on costs and profits. In the hands of policymakers, they can affect the operation of established markets or create new ones. They are commonly also referred to as 'economic' instruments because they attribute value to assets and directly affect decisions based on considerations of price and income.

### **Market-based/ Economic incentives**

Market-based approaches or incentives provide continuous inducements, monetary and near-monetary, to encourage polluting entities to reduce releases of harmful pollutants. As a result, market-based approaches create an incentive for the private sector to incorporate pollution abatement into production or consumption decisions and to innovate in such a way as to continually search for the least costly method of abatement.

### **Material flow accounting**

The quantification of all materials used in economic activities. It accounts for the total material mobilized during the extraction of materials and for the materials actually used in economic processes measured in terms of their mass.

### **Megacities**

Urban areas with more than 10 million inhabitants.

### **Merit goods**

Goods or services (such as education and vaccination) provided free for the benefit of the entire society by a government, because they would be under-provided if left to the market forces or private enterprise.

### **Merkel cell carcinoma**

A very rare disease in which malignant (cancer) cells form in the skin. Merkel cells are found in the top layer of the skin. These cells are very close to the nerve endings that receive the sensation of touch.

### **Methemoglobinemia**

A condition in which a higher-than-normal amount of methemoglobin is found in the blood. Methemoglobin is a form of hemoglobin that cannot carry oxygen. In methemoglobinemia, tissues cannot get enough oxygen. Symptoms may include headache, dizziness, fatigue, shortness of breath, nausea, vomiting, rapid heartbeat, loss of muscle coordination, and blue-colored skin. Methemoglobinemia can be caused by injury or being exposed to certain drugs, chemicals, or foods. It can also be an inherited condition.

### **Microbeads**

A tiny sphere of plastic (such as polyethylene or polypropylene).

### **Microbial and non-microbial contaminants**

Microbiological contamination refers to the non-intended or accidental introduction of microbes such as bacteria, yeast, mould, fungi, virus, prions, protozoa or their toxins and by-products. Prominent changes for product contamination include: loss of viscosity and sedimentation due to depolymerisation of suspending agents, pH changes, gas production, faulty smell, shiny viscous masses etc.

### **Microhabitat**

A habitat which is of small or limited extent and which differs in character from some surrounding more extensive habitat.

### **Microplastics**

Small plastic pieces, less than five millimeters long which can be harmful to our ocean and aquatic life.

### **Millennium Development Goals (MDGs)**

The eight Millennium Development Goals – which range from halving extreme poverty to halting the spread of HIV/AIDS and providing universal primary education, all by the target date of 2015 – formed a blueprint agreed to by all the world's countries and all the world's leading development institutions.

### **Monocultural farming systems**

The cultivation or growth of a single crop or organism especially on agricultural or forest land.

### **Morphology**

- (1) The physical characteristics of living organisms.
- (2) The branch of biology that deals with the form of living organisms, and with relationships between their structures.

### **Multilateral environmental agreements (MEAs)**

Treaties, conventions, protocols and contracts between several states regarding specific environmental problems.

### **Mycotoxin**

Mycotoxins are toxic compounds that are naturally produced by certain types of moulds (fungi). Moulds that can produce mycotoxins grow on numerous foodstuffs such as cereals, dried fruits, nuts and spices. Mould growth can occur either before harvest or after harvest, during storage, on/in the food itself often under warm, damp and humid conditions. Most mycotoxins are chemically stable and survive food processing.

### **Nanomaterial**

A natural, incidental or manufactured material containing particles, in an unbound state, as an aggregate or as an agglomerate and where, for 50 per cent or more of the particles in the number size distribution, one or more external dimension is in the size range 1–100 nanometres (a nanometre is one billionth of a metre). Such particles/materials are generally termed as nanoparticles, nanochemicals or nanomaterials.

### **Natural capital**

Natural assets in their role of providing natural resource inputs and environmental services for economic production. Natural capital includes land, minerals and fossil fuels, solar energy, water, living organisms, and the services provided by the interactions of all these elements in ecological systems.

### **Natural infrastructure**

Strategically planned and managed network of natural lands, such as forests and wetlands, working landscapes, and other open spaces that conserves or enhances ecosystem values and functions and provides associated benefits to human populations.

### **Natural resources**

Materials or substances such as minerals, forests, water, and fertile land that occur in nature and can be used for economic gain.

### Nature's Contribution to People

Nature's contribution to people (NCP) are all the contributions, both positive and negative, of living nature (i.e. diversity of organisms, ecosystems and their associated ecological and evolutionary processes) to the quality of life for people. Beneficial contribution from nature include such things as food provision, water purification, flood control and artistic inspiration, whereas detrimental contributions include disease transmission and predation that damages people or their assets. Many NCP may be perceived as benefits or detriment depending on the cultural, temporal or spatial context.

### Neonicotinoid

Neonicotinoids are an acetylcholine-interfering neurotoxic class of insecticides that are utilized in a variety of venues ranging from veterinary medicine, urban landscaping, and use in many agricultural systems as agents of crop protection. They can be applied by multiple methods as foliar sprays to above-ground plants, as root drenches to the soil, or as trunk injections to trees. However, it is estimated that approximately 60 per cent of all neonicotinoid applications globally are delivered as seed/soil treatments.

### Net primary production (NPP)

The rate at which all the plants in an ecosystem produce net useful chemical energy. Some net primary production goes toward growth and reproduction of primary producers, while some is consumed by herbivores.

### Neurotoxin

A poison which acts on the nervous system.

### Nitrogen deposition

The input of reactive nitrogen, mainly derived from nitrogen oxides and ammonia emissions, from the atmosphere into the biosphere.

### Non-Hodgkins lymphoma

Any of a large group of cancers of lymphocytes (white blood cells). Non-Hodgkin lymphomas can occur at any age and are often marked by lymph nodes that are larger than normal, fever, and weight loss. There are many different types of non-Hodgkin lymphoma. These types can be divided into aggressive (fast-growing) and indolent (slow-growing) types, and they can be formed from either B-cells or T-cells.

### Non-state actors

Non-state actors are categorized as entities that (i) participate or act in the sphere of international relations; organizations with sufficient power to influence and cause change in politics which (ii) do not belong to or exist as a state-structure or established institution of a state; do not have the characteristics of this, these being legal sovereignty and some measure of control over a country's people and territories.

### Normalized Difference Vegetation Index

To determine the density of green on a patch of land, researchers must observe the distinct colors (wavelengths) of visible and near-infrared sunlight reflected by the plants. As can be seen through a prism, many different wavelengths make up the spectrum of sunlight. When sunlight strikes objects, certain wavelengths of this spectrum are absorbed and

other wavelengths are reflected. The pigment in plant leaves, chlorophyll, strongly absorbs visible light (from 0.4 to 0.7  $\mu\text{m}$ ) for use in photosynthesis. The cell structure of the leaves, on the other hand, strongly reflects near-infrared light (from 0.7 to 1.1  $\mu\text{m}$ ). The more leaves a plant has, the more these wavelengths of light are affected, respectively.

### No-till (zero tillage)

A technique of drilling (sowing) seed with little or no prior land preparation, which has a positive impact on soil erosion.

### Nutrient pollution

Contamination of water resources by excessive inputs of nutrients.

### Nutrients

The approximately 20 chemical elements known to be essential for the growth of living organisms, including nitrogen, sulphur, phosphorus and carbon.

### Ocean Acidification

Term used to describe significant changes to the chemistry of the ocean. It occurs when carbon dioxide gas (or  $\text{CO}_2$ ) is absorbed by the ocean and reacts with seawater to produce acid. Although  $\text{CO}_2$  gas naturally moves between the atmosphere and the oceans, the increased amounts of  $\text{CO}_2$  gas emitted into the atmosphere, mainly as a result of human activities (e.g. burning fossil fuels), has been increasing the amount of  $\text{CO}_2$  absorbed by the ocean, which results in seawater that is more acidic.

### Ocean eutrophication

A process driven by the enrichment of water by nutrients, especially compounds of nitrogen and/or phosphorus, leading to: increased growth, primary production and biomass of algae; changes in the balance of organisms; and water quality degradation. The consequences of eutrophication are undesirable if they appreciably degrade ecosystem health and biodiversity and/or the sustainable provision of goods and services. Nitrogen and phosphorus are the primary inorganic nutrients responsible for the eutrophication of marine waters. Nitrogen and phosphorus occur naturally in marine waters, transferred from land via streams, rivers and runoff of rainwater and also from degradation of organic material within the water.

### Oceanography

The branch of science that deals with the physical and biological properties and phenomena of the sea.

### Organic agriculture

A production system that sustains the health of soils, ecosystems and people. It relies on ecological processes, biodiversity and cycles adapted to local conditions, rather than the use of synthetic inputs.

### Organic carbon (OC)

Organic carbon, as used in climate research, usually refers to the carbon fraction of the aerosol that is not black. This term is an oversimplification because organic carbon may contain hundreds or thousands of different organic compounds with varying atmospheric behaviour. It is the quantity that results from thermal analysis of carbon aerosols.

### **Organizations**

Bodies of individuals with a specified common objective. Organizations could be political organizations, political parties, governments and ministries; economic organizations, federations of industry; social organizations (non-governmental organizations (NGOs) and self-help groups) or religious organizations (church and religious trusts). The term organizations should be distinguished from institutions.

### **Organochlorine compounds**

Any of a class of organic chemical compounds containing carbon, hydrogen and chlorine, such as dioxins, polychlorinated-biphenyls (PCBs) and some pesticides such as DDT.

### **Outmigration**

The action of leaving one place to settle in another, especially within a country.

### **Overexploitation**

The excessive extraction of raw materials without considering the long-term ecological impacts of such use.

### **Overgrazing**

Excessive grazing (feeding of livestock) which causes damage to grassland.

### **Overshoot**

The situation that occurs when humanity's demand on the biosphere exceeds supply or regenerative capacity. At the global level, ecological deficit and overshoot are the same, since there is no net import of resources to the planet.

### **Oxidant**

An oxidizing agent.

### **Ozone layer**

A region of the atmosphere situated at an altitude of 10–50 km above the Earth's surface (called the stratosphere) which contains diluted ozone.

### **ozone-depleting substances (ODSs)**

Volatile organic compounds (VOC) are organic chemicals that when released into the atmosphere can react with sunlight and nitrogen oxides (NOx) to form tropospheric (ground-level) ozone. Two general classes of pesticide products contribute the vast majority of pesticidal VOC emissions: fumigants and emulsifiable concentrates.

### **Panacea**

A solution or remedy for all difficulties or diseases.

### **Participatory approach**

Securing an adequate and equal opportunity for people to place questions on an agenda and to express their preferences about a final outcome during decision making to all group members. Participation can occur directly or through legitimate representatives. Participation may range from consultation to the obligation of achieving a consensus.

### **Particulate matter (PM)**

Tiny solid particles or liquid droplets suspended in the air.

### **Pastoralism**

The husbandry of domestic animals as a primary means of obtaining resources.

### **Pasture**

Ground covered with grass or herbage, used or suitable for the grazing of livestock.

### **Pathogen**

A bacterium, virus, or other microorganism that can cause disease.

### **Payment for environmental services/payment for ecosystem services (PES)**

Appropriate mechanisms for matching the demand for environmental services with incentives for land users whose actions modify the supply of those environmental services.

### **Peatland**

Peatlands are a type of wetlands that occur in almost every country on Earth, currently covering 3 per cent of the global land surface. The term 'peatland' refers to the peat soil and the wetland habitat growing on its surface.

### **Per- and polyfluoroalkyl substances**

Per- and polyfluoroalkyl substances (PFAS) are a group of man-made chemicals that includes PFOA, PFOS, GenX, and many other chemicals. PFAS have been manufactured and used in a variety of industries around the globe, including in the United States since the 1940s. PFOA and PFOS have been the most extensively produced and studied of these chemicals. Both chemicals are very persistent in the environment and in the human body – meaning they don't break down and they can accumulate over time. There is evidence that exposure to PFAS can lead to adverse human health effects.

### **Perennial**

Lasting or existing for a long or apparently infinite time; enduring or continually recurring.

### **Peri-urban**

(Especially in Africa) denoting or located in an area immediately adjacent to a city or urban area.

### **Permafrost**

Soil, silt and rock located in perpetually cold areas, and that remains frozen year-round for two or more years.

### **Pernicious**

Having a harmful effect, especially in a gradual or subtle way.

### **Persistent organic pollutants (POPs)**

Chemical substances that persist in the environment, bioaccumulate through the food web, and pose a risk of causing adverse effects to human health and the environment.

### **Phenology**

The study of cyclic and seasonal natural phenomena, especially in relation to climate and plant and animal life.

### **Photoconjunctivitis**

Inflammation of the conjunctiva of the eye caused by exposure to UV.

**Photokeratitis**

Painful eye condition that occurs when your eye is exposed to invisible rays of energy called ultraviolet (UV) rays, either from the sun or from a man-made source.

**Phytoplankton**

Microscopically small plants that float or swim weakly in fresh or saltwater bodies.

**Planetary boundaries**

A framework designed to define a safe operating space for humanity for the international community, including governments at all levels, international organizations, civil society, the scientific community and the private sector, as a precondition for sustainable development.

**Plasticizers**

A substance (typically a solvent) added to a synthetic resin to produce or promote plasticity and flexibility and to reduce brittleness.

**Pneumonia**

Pneumonia is a bacterial, viral, or fungal infection of one or both sides of the lungs that causes the air sacs, or alveoli, of the lungs to fill up with fluid or pus. Symptoms can be mild or severe and may include a cough with phlegm (a slimy substance), fever, chills, and trouble breathing. Many factors affect how serious pneumonia is, such as the type of germ causing the lung infection, your age, and your overall health. Pneumonia tends to be more serious for children under the age of five, adults over the age of 65, people with certain conditions such as heart failure, diabetes, or COPD (chronic obstructive pulmonary disease), or people who have weak immune systems due to HIV/AIDS, chemotherapy (a treatment for cancer), or organ or blood and marrow stem cell transplant procedures.

**Policy diffusion**

The process of a policy being taken up, copied, implemented in other areas, fields, regions or sectors.

**Policy**

Any form of intervention or societal response. This includes not only statements of intent, but also other forms of intervention, such as the use of economic instruments, market creation, subsidies, institutional reform, legal reform, decentralization and institutional development. Policy can be seen as a tool for the exercise of governance. When such an intervention is enforced by the state, it is called public policy.

**Policymaker**

A member of a government department, legislature, or other organization who is responsible for making new rules, laws, etc.

**Pollutant**

Any substance that causes harm to the environment when it mixes with soil, water or air.

**Pollution**

The presence of minerals, chemicals or physical properties at levels that exceed the values deemed to define a boundary between good or acceptable and poor or unacceptable quality, which is a function of the specific pollutant.

**Polycentric**

Having many centres, especially of authority or control.

**Poverty**

The state of one who lacks a defined amount of material possessions or money. Absolute poverty refers to a state of lacking basic human needs, which commonly include clean and freshwater, nutrition, health care, education, clothing and shelter.

**Precautionary approach/principle**

The precautionary approach or precautionary principle states that if an action or policy has a suspected risk of causing harm to the public or to the environment, in the absence of scientific consensus that the action or policy is harmful, the burden of proof that it is not harmful falls on those taking the action.

**Prediction**

The act of attempting to produce a description of the expected future, or the description itself, such as "it will be 30°C tomorrow, so we will go to the beach."

**Premature deaths**

Deaths occurring earlier due to a risk factor than would occur in the absence of that risk factor.

**Primary energy**

Energy embodied in natural resources (such as coal, crude oil, sunlight or uranium) that has not undergone any anthropogenic conversion or transformation.

**Private sector**

The private sector is part of a country's economy which consists of industries and commercial companies that are not owned or controlled by the government.

**Projection**

The act of attempting to produce a description of the future subject to assumptions about certain preconditions, or the description itself, such as "assuming it is 30°C tomorrow, we will go to the beach."

**Protected area**

A clearly defined geographical space, recognized, dedicated and managed, through legal or other effective means, to achieve the long-term conservation of nature with associated ecosystem services and cultural values.

**Provisioning services**

The products obtained from ecosystems, including, for example, genetic resources, food and fibre, and freshwater.

**Pterygium**

Growth of the conjunctiva or mucous membrane that covers the white part of your eye over the cornea. The cornea is the clear front covering of the eye. This benign or noncancerous growth is often shaped like a wedge. A pterygium usually doesn't cause problems or require treatment, but it can be removed if it interferes with your vision.

### **Precision agriculture**

It involves the observation, impact assessment and timely strategic response to fine-scale variation in causative components of an agricultural production process. Therefore, precision agriculture may cover a range of agricultural enterprises, from dairy herd management through horticulture to field crop production. The philosophy can be also applied to pre- and post-production aspects of agricultural enterprises.

### **Public sector**

The portion of society that comprises the general government sector plus all public corporations including the central bank.

### **Public-private partnership**

A contractual agreement between a public agency (federal, state or local) and a private sector entity. Through such an agreement, the skills and assets of each sector (public and private) are shared in delivering a service or facility.

### **Quasi-equity**

A form of company debt that could also be considered to possess some traits of equity, such as being non-secured by any collateral.

### **Radiative forcing**

A measure of the net change in the energy balance of the Earth with space, that is, the change in incoming solar radiation minus outgoing terrestrial radiation.

### **REDD/REDD+**

Reducing Emissions from Deforestation and Forest Degradation in Developing Countries. REDD+ involves enhancing existing forests and increasing forest cover. In order to meet these objectives, policies need to address enhancement of carbon stocks by providing funding and investments in these areas.

### **Reforestation**

Planting of forests on lands that have previously contained forest, but have since been converted to some other use.

### **Regulating services**

The benefits obtained from the regulation of ecosystem processes, including, for example, the regulation of climate, water and some human diseases.

### **Remote sensing**

Collection of data about an object from a distance. In the environmental field, it normally refers to aerial or satellite data for meteorology, oceanography or land cover assessment.

### **Renewable energy source**

An energy source that does not rely on finite stocks of fuels. The most widely known renewable source is hydropower; other renewable sources are biomass, solar, tidal, wave and wind.

### **Resilience (Ecological)**

The capacity of a system to absorb disturbance and reorganize while undergoing change so as to still retain essentially the same function, structure, identity, and feedbacks.

### **Resilience-based management**

The focus on the processes that are essential to the ability of corals to withstand the effects of climate-related stress (resistance), and to recover (recruitment, growth survival) after major impacts.

### **Resistance**

The capacity of a system to withstand the impacts of drivers without displacement from its present state.

### **Resource management activities**

Activities related with the management of natural resources (monitoring, control, surveys, administration and actions for facilitating structural adjustments of the sectors concerned).

### **Riparian**

Related to or located on the bank of a natural watercourse, usually a river, but sometimes a lake, tidewater or enclosed sea.

### **River fragmentation**

Degree to which river connectivity and flow regimes have been altered, usually by dams and reservoirs.

### **Riverine**

Relating to or situated on a river or riverbank; riparian.

### **Run-off**

A portion of rainfall, melted snow or irrigation water that flows across the ground's surface and is eventually returned to streams. Run-off can pick up pollutants from air or land and carry them to receiving waters.

### **Sahel**

A loosely defined strip of transitional vegetation that separates the Sahara desert from the tropical savannahs to the south. The region is used for farming and grazing, and because of the difficult environmental conditions at the border of the desert, the region is very sensitive to human-induced land-cover change. It includes parts of Senegal, the Gambia, Mauritania, Mali, Niger, Nigeria, Burkina Faso, Cameroon and Chad.

### **Salinisation/salination**

The process by which water-soluble salts accumulate in the soil. Salinization may occur naturally or because of conditions resulting from management practices.

### **Sand and dust storms**

Sand and dust storms are common meteorological hazards in arid and semi-arid regions. They are usually caused by thunderstorms – or strong pressure gradients associated with cyclones – which increase wind speed over a wide area. These strong winds lift large amounts of sand and dust from bare, dry soils into the atmosphere, transporting them hundreds to thousands of kilometres away. Some 40 per cent of aerosols in the troposphere (the lowest layer of Earth's atmosphere) are dust particles from wind erosion. The main sources of these mineral dusts are the arid regions of Northern Africa, the Arabian Peninsula, Central Asia and China. Comparatively, Australia, America and South Africa make minor, but still important, contributions. Global estimates of dust emissions, mainly derived from simulation models, vary between one and three Gigatons per year.

**Scale**

The spatial, temporal (quantitative or analytical) dimension used to measure and study any phenomena. Specific points on a scale can thus be considered levels (such as local, regional, national and international).

**Scenario**

A description of how the future may unfold based on if-then propositions, typically consisting of a representation of an initial situation, a description of the key drivers and changes that lead to a particular future state. For example, "given that we are on holiday at the coast, if it is 30°C tomorrow, we will go to the beach."

**Seagrass bed**

Profusion of grass-like marine plants, usually on shallow, sandy or muddy areas of the seabed.

**Seamounts**

Underwater mountain formed by volcanic activity.

**Secondary pollutant**

Not directly emitted as such, but forms when other pollutants (primary pollutants) react in the atmosphere.

**Security**

Relates to personal and environmental security. It includes access to natural and other resources, and freedom from violence, crime and war, as well as security from natural and human-caused disasters.

**Sediment**

Solid material that originates mostly from disintegrated rocks and is transported by, suspended in or deposited from water, wind, ice and other organic agents.

**Sedimentation**

Strictly, the act or process of depositing sediment from suspension in water or ice. Broadly, all the processes whereby particles of rock material are accumulated to form sedimentary deposits. Sedimentation, as commonly used, involves transport by water, wind, ice and organic agents.

**Sequestration**

In GEO-5, sequestration refers to the capture of carbon dioxide in a manner that prevents it from being released into the atmosphere for a specified period of time.

**Sex-disaggregated data**

Sex-disaggregated data is data that is cross-classified by sex, presenting information separately for men and women, boys and girls. Sex-disaggregated data reflect roles, real situations, general conditions of women and men, girls and boys in every aspect of society. For instance, the literacy rate, education levels, business ownership, employment, wage differences, dependants, house and land ownership, loans and credit, debts, etc. When data is not disaggregated by sex, it is more difficult to identify real and potential inequalities. Sex-disaggregated data is necessary for effective gender analysis.

**Sharing economy**

The peer-to-peer-based activity of obtaining, giving, or sharing the access to goods and services, coordinated through community-based online services.

**Short-term climate forcers**

Substances such as methane, black carbon, tropospheric ozone, and many hydrofluorocarbons, which have a significant impact on climate change, and a relatively short lifespan in the atmosphere compared to carbon dioxide and other longer-lived gases.

**Siltation**

The deposition of finely divided soil and rock particles on the bottom of stream and riverbeds and reservoirs.

**Silvopastoral production systems**

The integration of trees and shrubs in pastures with animals for economic, ecological and social sustainability.

**Smart cities**

A smart city is a designation given to a city that incorporates information and communication technologies (ICT) to enhance the quality and performance of urban services such as energy, transportation and utilities in order to reduce resource consumption, wastage and overall costs. The overarching aim of a smart city is to enhance the quality of living for its citizens through smart technology.

**Social amenities**

Refer to places, buildings or infrastructural facilities which are to be shared and to become convergence spots for the local and surrounding communities. It has become a basic necessity for villages and settlement areas to have well-built and complete social amenities for the benefit of the local and surrounding communities, so as to facilitate them in conducting social functions and activities, which in turn would help shape a united, harmonious, advanced, dynamic and progressive society.

**Social ecological systems**

Complex adaptive systems composed of many diverse human and non-human entities that interact. They adapt to changes in their environment and their environment changes as a result.

**Social network**

A social structure made up of a set of actors, such as individuals or organizations, and the ties between these actors, such as relationships, connections or interactions.

**Socioeconomic**

Of, relating to, or involving a combination of social and economic factors.

**Soft law**

Rules that are neither strictly binding in nature nor completely lacking legal significance. They are weakened along one or more of the dimensions of obligation, precision and delegation. In the context of international law, soft law refers to guidelines, policy declarations or codes of conduct which set standards of conduct. However, they are not directly enforceable.

**Spawning (fisheries)**

To deposit or fertilize spawn; to produce young especially in large numbers.

**Species (biology)**

An interbreeding group of organisms that is reproductively isolated from all other organisms, although there are many partial exceptions to this rule. A generally agreed fundamental taxonomic unit that, once described and accepted, is associated with a unique scientific name.

**Species diversity**

Biodiversity at the species level, often combining aspects of species richness, their relative abundance and their dissimilarity.

**Species richness**

The number of species within a given sample, community or area.

**Spillover effect**

The trickle down of growth from one region to another.

**Stewardship**

The job of supervising or taking care of something, such as an organization or property.

**Strategic environmental assessment (SEA)**

A range of analytical and participatory approaches that aim to integrate environmental considerations into policies, plans and programmes and evaluate the links with economic and social considerations. An SEA is undertaken for plans, programmes and policies. It helps decision makers reach a better understanding of how environmental, social and economic considerations fit together.

**Stratospheric ozone depletion**

Chemical destruction of the stratospheric ozone layer, particularly by substances produced by human activities.

**Surface water**

All water naturally open to the atmosphere, including rivers, lakes, reservoirs, streams, impoundments, seas and estuaries. The term also covers springs, wells or other collectors of water that are directly influenced by surface waters.

**Sustainability**

A characteristic or state whereby the needs of the present population can be met without compromising the ability of future generations or populations in other locations to meet their needs.

**Sustainable agriculture**

Sustainable Agriculture puts the emphasis on methods and processes that improve soil productivity while minimising harmful effects on the climate, soil, water, air, biodiversity and human health. It aims to minimise the use of inputs from nonrenewable sources and petroleum-based products and replace them with those from renewable resources. It focuses on local people and their needs, knowledge, skills, socio-cultural values and institutional structures. It ensures that the basic nutritional requirements of current and future generations are met in both quantity and quality terms. It provides long-term employment, an adequate income and dignified and equal working and living conditions for everybody involved in agricultural value chains. It reduces the agricultural sector's vulnerability to adverse natural conditions (e.g. climate),

socioeconomic factors (e.g. strong price fluctuations) and other risks.

**Sustainable development**

Development that meets the needs of the present generation without compromising the ability of future generations to meet their own needs.

**Sustainable forest management (SFM)**

The stewardship and use of forests and forest lands in a way, and at a rate, that maintains their biodiversity, productivity, regeneration capacity, vitality and potential to fulfill, now and in the future, relevant ecological, economic and social functions, at local, national and global levels, and that does not cause damage to other ecosystems.

**Synergies**

These arise when two or more processes, organizations, substances or other agents interact in such a way that the outcome is greater than the sum of their separate effects.

**System**

A system is a collection of component parts that interact with one another within some boundary.

**Taxonomy**

A system of nested categories (taxa) reflecting evolutionary relationships or morphological similarities.

**TechnoGarden**

The TechnoGarden scenario depicts a globally connected world relying strongly on technology and highly managed, often engineered ecosystems, to deliver ecosystem services.

**Technology transfer**

A broad set of processes covering the flows of know-how, experience and equipment among different stakeholders.

**Technology**

Physical artefacts or the bodies of knowledge of which they are an expression. Examples are water extraction structures, such as tube wells, renewable energy technologies and traditional knowledge. Technology and institutions are related. Any technology has a set of practices, rules and regulations surrounding its use, access, distribution and management.

**Temperate region**

The region in which the climate undergoes seasonal change in temperature and moisture. Temperate regions of the Earth lie primarily between 30° and 60° latitude in both hemispheres.

**Theory of change**

A theory of change is a method that explains how a given intervention, or set of interventions, is expected to lead to specific development change, drawing on a causal analysis based on available evidence.

**Thermohaline circulation**

Large-scale density-driven circulation in the ocean, caused by differences in temperature and salinity. In the North Atlantic, the thermohaline circulation consists of warm surface water flowing northward and cold deep water flowing southward, resulting in a net poleward transport of heat. The surface

water sinks in highly restricted sinking regions located in high latitudes. Also referred to as the (global) ocean conveyor belt or the meridional overturning circulation.

**Threshold**

The level of magnitude of a system process at which sudden or rapid change occurs. A point or level at which new properties emerge in an ecological, economic or other system, invalidating predictions based on mathematical relationships that apply at lower levels.

**Tipping point**

The critical point in an evolving situation that leads to a new and sometimes irreversible development.

**Top-down**

Used to refer to a situation in which decisions are made by a few people in authority rather than by the people who are affected by the decisions.

**Topography**

The study or detailed description of the surface features of a region.

**Traditional or local ecological knowledge**

A cumulative body of knowledge, know-how, practices or representations maintained or developed by peoples with extended histories of interaction with the natural environment.

**Transformation**

State of being transformed. In the context of GEO-5, transformation refers to a series of actions that explores opportunities to stop doing the things that pull the Earth System in the wrong direction and at the same time provide resources, capacity and an enabling environment for all that is consistent with the sustainable-world vision.

**Transformational change**

The process whereby positive development results are achieved and sustained over time by institutionalizing policies, programmes and projects within national strategies. It should be noted that this embodies the concept of institutionally sustained results – consistency of achievement over time. This is in order to exclude short-term, transitory impact.

**Transformative pedagogy**

A progressive educational approach that includes democratic constructivist-based pedagogy for the promotion of social justice and democratic ideals to transform students and society. Transformative pedagogy empowers learners to engage in dialogue to co-construct meaning from educational material and experiences through an inquiry-based approach (as opposed to what Paulo Freire calls a “banking” orientation). It also promotes personal experiences, dialogical pedagogy, and aligning education with social justice.

**Transitions**

Non-linear, systematic and fundamental changes of the composition and functioning of a societal system with changes in structures, cultures and practices.

**Transpiration**

The loss of water vapour from parts of plants, especially in leaves but also in stems, flowers and roots.

**Trillion**

10<sup>12</sup> (1 000 000 000 000).

**Trophic level**

Successive stages of nourishment as represented by the links of the food chain. The primary producers (phytoplankton) constitute the first trophic level, herbivorous zooplankton the second and carnivorous organisms the third trophic level.

**Tropospheric ozone**

Ozone at the bottom of the atmosphere, and the level at which humans, crops and ecosystems are exposed. Also known as ground-level ozone.

**Urban agglomeration**

The population contained within the contours of a contiguous territory inhabited at urban density levels without regard to administrative boundaries.” In other words, it integrates the ‘City Proper’ plus suburban areas that are part of what can be considered as city boundaries; a term that in itself is controversial.

**Urban sprawl**

The decentralization of the urban core through the unlimited outward extension of dispersed development beyond the urban fringe, where low density residential and commercial development exacerbates fragmentation of powers over land use.

**Urbanism**

An integration of urban and rural development in terms of sustainable resource use and the convergence of human well-being.

**Urbanization**

An increase in the proportion of the population living in urban areas.

**Venture capital**

Venture capital is capital that is invested in projects that have a high risk of failure, but that will bring large profits if they are successful.

**Virtual water trade**

The idea that when goods and services are traded, the water needed to produce them (embedded) is traded as well.

**Volatile Organic Compounds (VOCs)**

Volatile organic compounds (VOC) means any compound of carbon, excluding carbon monoxide, carbon dioxide, carbonic acid, metallic carbides or carbonates and ammonium carbonate, which participates in atmospheric photochemical reactions, except those designated by EPA as having negligible photochemical reactivity.

**Vulnerability**

An intrinsic feature of people at risk. It is a function of exposure, sensitivity to impacts of the specific unit exposed (such as a watershed, island, household, village, city or country), and the ability or inability to cope or adapt. It is multi-dimensional, multi-disciplinary, multi-sectoral and dynamic. The exposure is to hazards such as drought, conflict or extreme price fluctuations, and also to underlying socio-economic, institutional and environmental conditions.

**Wastewater treatment**

Any of the mechanical, biological or chemical processes used to modify the quality of wastewater in order to reduce pollution levels.

**Water column**

An imaginary column extending through a water body from its floor to its surface.

**Water quality**

The chemical, physical and biological characteristics of water, usually in respect to its suitability for a particular purpose.

**Water scarcity**

Occurs when annual water supplies drop below 1 000 m<sup>3</sup> per person, or when more than 40 per cent of available water is used.

**Water security**

A term that broadly refers to the sustainable use and protection of water systems, the protection against water related hazards (floods and droughts), the sustainable development of water resources and the safeguarding of (access to) water functions and services for humans and the environment.

**Water stress**

Occurs when low water supplies limit food production and economic development, and affect human health. An area is experiencing water stress when annual water supplies drop below 1 700 m<sup>3</sup> per person.

**Wetland**

Area of marsh, fen, peatland, bog or water, whether natural or artificial, permanent or temporary, with water that is static or flowing, fresh, brackish or salt, including areas of marine water to a depth, at low tide, that does not exceed 6 metres.

**Whole-genome sequencing**

A laboratory process that is used to determine nearly all of the approximately 3 billion nucleotides of an individual's complete DNA sequence, including non-coding sequence.

**Wildlife**

Wild animals collectively; the native fauna (and sometimes flora) of a region.

**Woodland**

Wooded land, which is not classified as forest, spanning more than 0.5 hectares, with trees higher than 5 metres and a canopy cover of 5–10 per cent, or trees able to reach these thresholds *in situ*, or with a combined cover of shrubs, bushes and trees above 10 per cent. It does not include areas used predominantly for agricultural or urban purposes.

**Zettabyte**

A unit of information equal to one sextillion (10<sup>21</sup>) or, strictly, 2<sup>70</sup> bytes.

**Zika**

A mosquito-borne virus of the genus *Flavivirus* (family *Flaviviridae*), found in parts of Africa and in Malaysia; it causes Zika fever.

**Zoonotic disease**

(Also known as zoonosis) An infection or disease that is transmissible from animals to humans under natural conditions.

"The sixth Global Environment Outlook is an essential check-up for our planet. Like any good medical examination, there is a clear prognosis of what will happen if we continue with business as usual and a set of recommended actions to put things right. GEO-6 details both the perils of delaying action and the opportunities that exist to make sustainable development a reality." -

**António Guterres**, Secretary-General of the United Nations

Published to coincide with the Fourth United Nations Environmental Assembly, UN Environment's sixth Global Environment Outlook (2019) calls on decision makers to take bold and urgent action to address pressing environmental issues to achieve the Sustainable Development Goals as well as other Internationally Agreed Environment Goals, such as the Paris Agreement.

UN Environment launched the first Global Environment Outlook (GEO) in 1997. By bringing together a community of hundreds of scientists, peer reviewers and collaborating institutions and partners, the GEO reports build on sound scientific knowledge to provide governments, local authorities, businesses and individual citizens with the information needed to guide societies to a truly sustainable world by 2050.

GEO-6 builds on the findings of previous GEO reports, including the six regional assessments (2016), and outlines the current state of the environment, illustrates possible future environmental trends and analyses the effectiveness of policies. This flagship report shows how governments can put the world on the path to a truly sustainable future. It emphasizes that urgent and inclusive action is needed by decision makers at all levels to achieve a healthy planet with healthy people.
